Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 27, 1895.

THE

ELECTRICAL ENGINEER,

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XVI. (NEW SERIES.)

FROM JULY 5, 1895, TO DECEMBER 27, 1895.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1895.

Digitized by Google

INDEX TO VOL. XVI. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Abdank's Hysteresis Compensator, **452**
Aberdeen Electricity Works, **258, 267**
Accidents, 1, 57, 227, 309, 337, 521, 577, 669, 720
Accidents in Mines, Prevention of, 197

Accumulators:
Austria, The, 31
Boron, 605
Boxes, New Use for (Smuggling Goods), 57
Cologne, The, 547
Constant, A New, 310
Gabarro, The, **76**
v. Gas-engines, 670, 699
Hatch, The, 671
History, Manufacture, etc., H. A. Earle, **326**
Lead-Powder, 666
New American (Lead and Pumice Stone), 549
Patent Disputes in Germany, 670
Renault, The, 114
v. Resistance Coils, 609
"Sand," 172
Theory of Darrieus, 173
Thermo-Chemical Carbon, 226
Velvo-Carbon, **104**

Accumulator Traction in Germany and Holland, 381
Acetic Acid, Purification of, by Electricity, 113
Acetylene, 605, 669
Addition of Lead to Copper to increase Fluidity, 465
Advance of the Electric Railway Motor, **565**
Aerial Railway in Berlin, 226
African Chiefs and Electricity, 437
Agencies, 23, 51, 110, 191, 357, 374, 406, 572
Air Pump, An Automatic Mercurial, 578
Alioth Alternating-Current Dynamo, **119**
Alkali Process, The Castner-Kellner, 466, 497
Almanacs, etc., Received, 740
Alternate-Current Transformers, Dr. Fleming's Lectures, 726
Alternating Current, Application of, to Railway Work, 494
Alternating Currents, Theory of, **6, 66**
Alternators, *see* DYNAMOS
Aluminium, 309, 725
Aluminium Company and the Falls of Foyers, *see* POWER TRANSMISSION
Amazon Cable, The, 54, 337, 410, **514, 679**
American Institute of Electrical Engineers, **16**
Americans Again (Electric Weed Killer), 225
Ampere's Blackboard, 605
Ananias at it Again (Sand Battery for Incandescent Lamp), 172
An Extraordinary Case (Leading Article), **422**
Angling by Electric Light, 494
Anglo-Foreign Technical Dictionaries, 644
Another (New American Contemporary), 86
Anthony, W. A., Street Car Propulsion, **272**
Appointments, 22, 58, 191, 194, 276, 303, 375, 458, 516, 544, 571, 572, 573
Appointments Vacant, 23, 52, 80, 250, 276, 333, 406, 430, 516, 602, 663, 692, 720, 742
Archbutt-Deeley Water Purifying and Softening Process, 601
Archduke Carl Ludwig and the Electrotechnischer Verein in Vienna, 521

Arc Lamps:
Cost of, per year, 465
Jandus, The, **481, 508**
for Lantern Lectures, 406
Niewerth, The, 697
Reflectors, 31
Richardson I.R., **689**
Ross-Hepworth, **447**

Arc Light, S. P. Thompson, **530, 545, 659, 735**
Are you There? (Telephoning to the Moon), 80
Argon, 310, 466, 549, 697
Armatures, Fields, etc., Location of Grounds in, C. E. Gifford, **235**
Armour Plates, Electric Annealing of, 469
Aron, Dr., Lamp for Optical Experiments, 493
Atkinson, L. B., Distribution of Power in Collieries, 737
Asphalte Cables, Durability of, 381
Association of Municipal Engineers, 170, **204, 212, 237, 245, 272**
Audits of Accounts of Electric Lighting Companies, 744
Autocars, 169, 170, 199, 201, 225, 282, 382, 439, **453**, 493, 522, 550, 577, 605, 643, 672, 673
Automatic Marine Fog Signal, 58
Awards, 86, 143, 199, 549, **554**, 697
Ayrton, Prof., and T. Mather, A Portable Magnetic-Field Tester, **317**

B.

Bain, F., A Successful and Simple Method for Preventing Electrolytic Decomposition by Railway Currents, **526**
Baker, Sir B., Inaugural Address at Institution of Civil Engineers, **564**
Balloon Society, 170
Bankers' Strong-room, Electrically Fitted, 431

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XVI. LONDON, JULY 5, 1895. PRICE 3D.

NOTES.

The Kiel Fetes.—The electric illuminations of the British men-of-war seem to have been exceptionally tasteful.

The Copenhagen-Hamburg Telephone line will be opened this month, when work will at once be commenced on the extension to Berlin.

Book Received.—"Notes on Submarine Telegraph Cable Work: Grappling," by Walter Goodsall, late commander of the Eastern Telegraph Company's s.s. "Chiltern," illustrated by the author (1s.).

More Electrical Exhibitions.—Negotiations are being made for the organisation of an exposition of electrical appliances at Reims, while the North German Commercial and Industrial Exhibition, which has just been opened at Lübeck, has a considerable electrical section.

The Proposed Pacific Cable.—A Reuter telegram says that the vice-president of the San Francisco Chamber of Commerce is convinced that a Pacific cable will shortly be laid by a group of British capitalists, and that the route chosen is from Auckland to Vancouver, by way of Norfolk Island, Fiji, and Fanning Island.

Institution of Civil Engineers.—The council of the Institution of Civil Engineers have reappointed as treasurer Mr. Hugh Lindsay Antrobus, the senior partner in Messrs. Coutts and Co.; as honorary secretary, Dr. William Pole, F.R.S.; and as the secretary, Mr. James Forrest, which office he has filled for the past 39 years.

Electric Meter Trials in Paris.—Our note on this subject in last week's issue, p. 731, must be subjected to a correction. The French journal from which we borrowed the account of the trials states in its latest number that the number of failures attributed to the Aron meter should, instead of 15 per cent., be 16 per 1,000, or 1·6 per cent.

Niagara.—A telegram from New York states that electric power transmitted for commercial purposes from Niagara Falls was sent on Tuesday through the electrical subway to a manufactory a mile distant. Four thousand horse-power was delivered and used in an aluminium establishment. The telegram adds that a rapid extension of the Niagara Power Company's operations is expected.

Electric Railway for Oberammergau.—Oberammergau, of Passion Play renown, is to have its electric railway. Messrs. O. L. Kummer and Co., of Dresden, have obtained a ministerial concession for the construction of a line between Murnau and Ammergau by way of Kohlgrub. It is also proposed to supply electric power for lighting and industrial purposes to places contiguous to the railway.

Electricity in Mining.—The use of electricity in South African mining operations continues to steadily increase. A report from the Sheba Mine states that extensive alterations are being made in connection with the new electric installation, while at the City and Suburban Mine a dynamo is being placed in the workshops to supersede the present shop engine, which is driven by the boilers of the old plant.

Electric Fatality.—Carelessness has begot another fatal accident. A fitter in the employ of the Internationale Elektrizitäts-Gesellschaft, of Vienna, has been killed by an electric current while handling some wires in the cellar of a palace in the Ringstrasse. The unfortunate man omitted to wear the prescribed pair of indiarubber gloves. He was seen suddenly to stick to the wires, the fingers of the left hand were burnt to the bone, and he dropped dead in a few seconds.

On the Continent.—The electrical industry seems to be flourishing in Central Europe, if we may judge from newspaper reports. Messrs. Schuckert and Co., of Nuremberg, it is reported, are so well supplied with orders for both lighting and traction work, at good prices, that they are engaging a large number of fresh hands. Italy, British firms might note, is stated to be offering the best field for German electrical enterprise at present. Then the formation of still another electrical trust company is announced from Budapest. This new company is to be financed by the Ungarische Kommerzialbank, and will be connected with the Berlin Allgemeine Elektricitäts-Gesellschaft.

Opposition to Electric Tramways.—An episode in connection with the proposed electric tramways in Quebec reminds one of the pother caused through the supersession of stage coaches by steam-hauled carriages; and also, in a less degree, of the artisanal opposition to the introduction of the spinning-jenny. It seems that the blacksmiths, horseshoers, harnessmakers, and hackdrivers of Quebec have made an energetic protest against the granting of a permit to build an electric tramway in that city, for the reason that it will interfere with their means of earning a living. There is sound common sense in the saw that counsels a man not to beat his head against a stone wall.

Electric Traction for Bombay.—On the subject of Madras tramways, a correspondent of *Indian Engineering* points out that if direct steam propulsion on the Batavian model is adopted for Madras the electric plant would be found extremely serviceable at Bombay, where the conditions are very favourable for electrical traction. The Bombay tramways are now horsed, but the expense must be heavy, and waste of animal life (as with all tramways) excessive. There is little fear of the wires being blown down by a cyclone; overhead wires can be supported without, as a rule, causing any obstruction to traffic, while the Bombay tram routes are for the most part straight and lengthy runs with few complicated junctions. In consequence, the electric system would answer and promise to pay well at Bombay.

The Electrostatic Capacity of Coils.—A paper with this title was recently communicated by M. J.

Digitized by Google

Cauro to the Académie des Sciences (*Comptes Rendus*, 1895, p. 308). As is known, coils that are double wound may be regarded as possessing a capacity which increases rapidly with the resistance, but as having a self-induction which is small enough to be negligible. In the ordinary method of estimating self-induction, the algebraic sum of the self-induction and the capacity is ascertained, and since capacity is equivalent to a negative self-induction, the result of such a measurement may be either positive or negative. If positive, the algebraic sum may be made equal to zero by the introduction of a sufficient amount of paraffin to increase its capacity; if negative, the self-induction may be increased by the introduction of a suitable soft iron core. The capacity may be considerable, and must be eliminated whenever the elimination of self-induction is considered necessary. M. Cauro states that in his attempts to reduce the combined effect of self-induction and capacity in resistance coils, he has obtained excellent results by starting the winding of alternate layers of wire from the same end of the bobbin.

The Iron and Steel Institute.—The following is a list of the papers which it is expected will be read during the autumn meeting of the Iron and Steel Institute, which takes place in Birmingham on August 21, 22, and 23 next: (1) "The Direct Puddling of Iron," by E. Bonehill; (2) "The Thermo-Chemistry of the Bessemer Process," by Prof. W. N. Hartley, F.R.S.; (3) "The Hardening of Steel," by H. M. Howe; (4) "The Mineral Resources of South Staffordshire," by H. W. Hughes, A.R.S.M., F.G.S.; (5) "The Iron Industry of South Staffordshire," by D Jones, secretary of the South Staffordshire Ironmasters' Association; (6) "Tests of Cast Iron," by W. J. Keep; (7) "Small Cast Ingots," by R. Smith-Casson; (8) "The Estimation of Oxide of Iron in Steel," by A. E. Tucker, F.I.C.; (9) "Tests of Cast Iron," by T. D. West; (10) "The Use of Nickel in the Metallurgy of Iron," by H. A. Wiggin. The chairman of the local reception committee in Birmingham is Sir Benjamin Hingley, Bart., member of council of the Iron and Steel Institute; the treasurer is Mr. Arthur Keen, member of council of the Iron and Steel Institute; and the hon. secretary is Mr. Leigh H. Elkington, 10, Newhall-street, Birmingham.

The Institution Conversazione.—The conversazione of the Institution of Electrical Engineers, which took place in the galleries of the Royal Institute of Painters in Water Colours, in Piccadilly, W., on Wednesday evening, was numerously attended by members and their friends, who were received by the president of the Institution, Mr. R. E. B. Crompton. An addition to the ordinary attractions of the galleries was provided by the band of the Royal Horse Guards (Blue), under the conductorship of Mr. Charles Godfrey. The gathering was a very successful one. Among the guests were: Prof. W. Grylls Adam, F.R.S; Prof. W. E. Ayrton, F.R.S.; Mr. G. L. Bristow; Sir James Crichton-Browne, F.R.S.; Mr. H. W. Christmas, Consul-General for Servia; Prof. W. Crookes, F.R.S.; Sir David Dale, Bart.; Mr. Henry Edmunds, president Northern Society of Electrical Engineers; Mr. W. B. Esson; Sir John Evans, K.C.B., F.R.S.; Prof. G. Carey Foster, F.R.S.; Mr. S. Z. de Ferranti; Prof. George Forbes, F.R.S.; Mr. Robert Kaye Gray; Sir Thomas Gordon; Dr. J. H. Gladstone, F.R.S.; Lord Greenock; Prof. D. E. Hughes, F R.S.; Dr. John Hopkinson, F.R.S.; Charles Hawksley; Dr. Vernon Harcourt, F.R.S.; Lord Kelvin, P.R.S.; Mr. P. V. Luke, C.I.E.; Mr. W. M. Mordey; Sir Henry Mance, C.I.E.; Mr. Kenric B. Murray; Sir Colin Scott Moncrieff; Prof. Perry, F.R.S.; Mr. C. E. Spagnoletti; Sir David Salomons, Bart., M.A.; Mr. Alexander Siemens; Mr. Carl von Siemens; Prof. S. P. Thompson, F.R.S.; General Webber, C.B., M.I.C.E.; Mr. E. Woods, past-president Inst.C.E.

A Queer Case.—It is not often that diabolically ingenious attempts to damage the machinery of a manufacturer such as those which have been alleged at the Greenock Court against one John Whitelaw are brought to light. This person was charged with "having formed a wilful and malicious scheme for injuring the trade carried on by John Henry Cox, electroplater and engineer, 13, Nicholson-street, Greenock, the property and machinery there, and interfering with the working of his machinery and the peaceful carrying on of the business at the said premises." It is stated that the defendant, between January 1, 1893, and August 31, 1893, bored holes in the floor of his (accused's) workshop at 13, Nicholson-street, and through these holes repeatedly poured, or caused to flow, water into the workshop below occupied by Mr. Cox in order to damage certain polished articles therein and interfere with the working of a polishing lathe, and that at the same time and place the accused of intent dropped a heavy iron weight on the floor of his workroom with the effect of slackening the fastenings of the machinery in Mr. Cox's workshop. Other counts include a charge of having between March 1, 1894, and April 10, 1895, loosened a bolt in the floor of his workshop fastening a travelling crane in Mr. Cox's workshop for the purpose and with the effect of causing the crane to fall and be damaged, whereby the life of Archibald Dallis, apprentice engineer, was endangered. The case has aroused great interest in electroplating circles, and the hope is generally expressed that, if the charges be substantiated, the offender will receive just punishment for his contemptible acts.

Electric Lighting in Calcutta.—Electric lighting in the city of palaces cannot, *Indian Engineering* complains, be brought to bear on the darkness without a special legislative Act enacting provisional orders for the supply of electricity. The Indian Telegraph Act of 1885, under which licenses have been granted to telephone companies, has no application. Neither has Act XIII. of 1887, which was passed to provide for the protection of person and property from the risks incidental to the supply and use of electricity, but which does not provide for the grant of licenses. As a matter of hard fact, our contemporary asserts, it provides effectually for nothing at all. The new Bill now on the legislative anvil closely follows the English Act of 1882, though, since it is intended to empower the local government to grant licenses only, all references to "provisional orders" and "special Acts" have been omitted from the document; throughout which the Bengal Government has been substituted for the Board of Trade, as one of the high contracting parties. The definition of Calcutta limits is derived from the Calcutta Municipal Act of 1884, but in that Bill power is given to extend its provisions to the Howrah Municipality. Necessary powers for blocking streets, etc., for the purpose of supplying electricity within the area specified by the license have been, for the most part, adopted from the Gasworks Clauses Act of 1871. "Let us hope," the journal concludes, "that the new electric lighting scheme will pass legislative muster without any more obstructiveness from a jealous gas company, without exciting any more municipal feuds, and redundantly to the credit of everyone concerned with a creditable apportionment of municipal moneys."

Scope for Electricity in Japan.—A correspondent who has recently returned from a visit to the East emphasises the need of electric railways in Japan. Tokio, he says, has now considerably more than a million inhabitants. It is only 14 miles distant from Yokohama, the

Digitized by Google

intermediate country is thickly populated, and he is quite certain that an electric railway between the two points would pay. At present there are no electric railways in Tokio, and there are no tramway lines in Yokohama. Take the town of Osaka, in the central part of the empire, he continues; it has, with its suburbs, an enormous population, and there is not an electric railway in it. It is 16 miles from the coast, and is connected by railway with the town of Kobe. Kobe was very small at the time that Japan was first opened to foreign trade, but according to the census of 1890 it contained 136,000 people. An electric railway between Kobe and Osaka ought to prove a remunerative undertaking. This part of Japan is one succession of villages, and only a few miles west of Osaka is the great city of Kioto, which was for years the capital of Japan. If an electric line were laid from Kobe to Osaka, and thence to Kioto, it would touch villages at almost every mile of its course, and it would accommodate a population of fully 2,000,000 people. The Japanese are great travellers. They make long excursions over the country in order to visit the most sacred Buddhist temples and Shinto shrines, and hundreds of families are met walking along the roads from one sacred place to another. The railway carriages are well filled, and electric lines would pick up many parties out on these trips of combined religion and pleasure. As to the electric light field, the correspondent concludes, that is also great.

British Telephone Trunk Lines.—The telephone trunk-wire system of the Post Office was definitively inaugurated on Monday, when Mr. Spencer Walpole (secretary to the Post Office) and Mr. W. H. Preece (engineer-in-chief and electrician) spoke over the wires from London to gentlemen in Manchester, Liverpool, Birmingham, Leeds, Hull, Bristol, Cardiff, Derby, Newcastle-on-Tyne, Leicester, Nottingham, Plymouth, and Sheffield. We gave some particulars of the provisional opening of the new service in our issue of June 14, p. 677, and upon that occasion civic amenities were exchanged, mayoral jokes were cracked over the wires, and the soothing strains of a bagpipe were borne along the line from Glasgow; while one or two municipal officials adroitly utilised the opportunity to sound the London staff, much to its consternation, as to when replies might be expected to certain written communications. It was a subject of comment that the telephones did not seem to work quite so well when it was endeavoured to obtain an answer to these interrogations. It is, perhaps, natural that Austrian electrical engineers should manifest considerable satisfaction that our postal authorities have adopted the Deckert transmitter for the trunk lines. The *Zeitschrift für Elektrotechnik*, the organ of the Vienna Elektrotechnischer Verein, for example, talks of a "victory for Austrian industry"; while congratulations have poured in upon Herren Deckert and Homolka, of Vienna, the inventors and makers of the graphite loud-speaking microphone which is named after the head of the firm. It may be mentioned that the scale of charges laid down in the Treasury minute for a telephonic conversation of three minutes is as follows: for any distance not exceeding 20 miles, 3d.; for any distance exceeding 20 miles and not exceeding 40 miles, 6d.; for every additional 40 miles, or fraction thereof, 6d. Where a submarine cable is used, or where exceptional expense is incurred, an additional charge may be made.

The Drawback Telephone.—The *Electrical Age* of New York is the journal whose enterprise—we have it on its own authority—"stands out in strong relief against the lethargy of the oldest electrical papers;" it is the journal which conceived the ingenious idea of publishing a "Married" column, and it is the journal whence we extract, without apologies, the following interesting and instructive paragraph: "The Drawbaugh Telephone and Electric Company, of Reading, Pa., has been organised to manufacture, buy, rent, lease, and sell electric and magnetic telephones, electric machinery, and novelties, and also to buy, lease, rent, and erect telephone lines and exchanges, and to manufacture, buy, and sell telephone supplies and engage in and prosecute a general telephone business, using and operating telephones. Messrs. C. W. Ream and G. Milton Bair, 17, North Sixth-street, Reading, Pa., are the sole owners of the latest devices in telephones invented by Daniel Drawbaugh, the original inventor of telephones, and are actively engaged in presenting the merits and advantages of the new Drawbaugh telephone to the public. They have received permission from the Postal Telegraph Cable Company to use their poles within the city limits, and tests of great variety are made. The instrument used is a district, or short-distance phone. The Drawbaugh phone is claimed to be superior to any other because of its transmitter, which is a simple arrangement, consisting of a sponge always adjusted and between the plates a carbon. There is no induction, and sound is conveyed under seemingly the most adverse circumstances. A test was made by Mr. Bair, who stood 5ft. away from the phone and yet could be distinctly understood. He turned his back on the phone and his voice was heard, and he then closed the transmitter with his handkerchief, and still his voice could be plainly heard. A watch was held 3in. away from the phone and the ticking was plainly distinguished at the other end of the line. These tests cannot, it is said, be made with any other phone, because they have tried 30 kinds and all failed."

Electric Headlights.—Considerable progress has, it appears, been made in the Western States with electric headlights for locomotives, and Mr. G. C. Pyle, of Indianapolis, who has been identified with this work, has just brought out (our contemporary, the New York *Electrical Review*, says) an improved combination for this service, in which the mechanism is simplified and the wear consequently reduced. These generators are customarily mounted on the top of the smoke-box, behind the headlight projector, and either before or behind the stack. The dynamo is driven by a compound steam turbine of high speed, and the apparatus is described as follows: The steam is expanded four times before it is exhausted into the atmosphere. The governor is on the turbine wheel. The dynamo and turbine are on one base-plate, which is attached to the engine in such a manner as to preserve the alignment. The armature and commutator, which weigh but 23lb., are on the engine shaft, which runs at 2,000 revolutions a minute. The electrical balance of the dynamo is said to be so perfect that no spark can be seen at the brushes. The electric lamp can be placed in any ordinary headlight reflector by removing the oil lamp. Only one carbon is employed, a short piece of copper being used for the negative electrode. The entire plant is 19in. long, and weighs 211lb., the weight of the lamp being 15lb. The only wearing surface is the shaft, and this runs in oil. The two bearings are 3½in. and 6½in. long, and the weight of shaft, armature, and turbine wheel is but 40lb. As there are no internal wearing parts requiring oil, it is not considered necessary to supply a sight-feed lubricator in the cab for the dynamo. One ⅝in. carbon, costing 1¼ cent, will run about eight hours, which, it is asserted, practically constitutes the expense of running the light for that length of time. Among the claims made for the device are that in operating the plant dry or wet steam may be used, and it is said to make no difference if a full head of high-pressure steam is suddenly turned on, as there can be no reaction

Digitized by Google

or backlash. The whole mechanism may be started with one turn of a ½in. valve.

Electrical Thief-Traps.—A smart capture of what Americans call a sneak-thief by the medium of an electrical detector designed by Mr. G. H. O'Connor, of Chicago, is reported from that city. On the fifth floor of a large manufactory is a department employing a number of girls, who had been complaining for several months of thefts committed in their dressing-room on the sixth floor while they were at work. Silk handkerchiefs, veils, and money disappeared with increasing frequency, until at length the management began to realise that it was time steps were taken to secure the delinquent. As the dressing-room was kept locked, the key being accessible only to those engaged in the department where the losses were reported, it was decided that one of the girls using the room was rifling the pockets of the others. A trustworthy girl was accordingly taken into the confidence of the management; a double wire was sewn in the lining of her cloak, connecting a spring jaw in the pocket with the two hooks on which the cloak hung. The jaws were placed in contact with one of the wires and insulated from each other by a small tongue of leather placed between them while forced apart, and this tongue, again, was sewn to the bottom of a purse. Each of the two brass hooks supporting the garment was held in place by a long brass screw which went through the partition and connected with a wire on the outside of the dressing-room. Here the wires were carried under a moulding, through the floor, to a single-cell battery, and a bell, placed in series, was hidden in the room where the girls were at work 50ft. away. A switch was placed in a convenient position, which broke the circuit, until the other arrangements were completed. After closing the switch the only opening in the circuit was at the spring jaws, which would be brought together by removing the purse and insulating tongue. The trap had been set but three hours when the bell rang vigorously and the owner of the cloak hurried to the dressing-room and there found the guilty girl, who was immediately accused of theft and discharged after she had admitted the offence. Why a real detective was not called in to complete the admirable work of the electrical thief-catcher, and thus prevent the maiden with pilfering propensities from pursuing her malpractices in some other factory, remains a mystery.

Three-Phase Installations.—An interesting power-transmission plant is in course of installation at Bayonne, N.J., where the three-phase system of the General Electric Company will be employed to operate the machinery of the Tide Water Oil Company. This company is allied with the Standard Oil Company, and is engaged in exporting the refined products of petroleum. The nature of the process is such that spark-proof apparatus is imperative, and multiphase apparatus was selected as best fulfilling the peculiar conditions. The generator will be a 550-volt three-phase General Electric machine, having eight poles and a capacity of 75 kilowatts. The several induction motors will be of 5 h.p., 10 h.p., and 15 h.p. Some of these are spark-proof, and have a permanent resistance in the armature circuit. A peculiar interest attaches to these motors, as they will be employed in places where there exists an ever-present danger of explosion from gases, which a spark could readily ignite. They will be used to operate pumps, elevators, and other machinery. The switches will be of special construction, with blades immersed in oil. The generator also supplies current for about 525 lights scattered throughout the different parts of the works. Regulation of the lighting circuits will be effected by revolving regulators of novel design. Its first application of the three-phase long-distance system to tramway work will be made by the General Electric Company at Lowell, Mass., where a plant is in course of construction for the Lowell and Suburban Street Railway Company. In the first place, the generators will deliver both alternating and continuous current, and when not in use for transmission work will be run in parallel with the railway generators now in the station. They will be wound for low-voltage current at the alternating side, and this current, raised to 5,000 volts, will be carried to two sub stations—one nine miles and the other 14 miles distant from the generating station. Each sub-station will be provided with step-down transformers of the air-blast type and two rotary converters. These machines are constructed to maintain at the commutator brushes 5,000 volts at no load and 550 volts at full load. Another transformer sub-station for 400 incandescent lamps will be installed six miles from the generators. The success of this plant, the *Western Electrician* remarks, will go far towards solving the problem of the operation of railways over long distances, taking the current from one power station.

Direct Production of Electricity from Hydrogen. Mr. H. H. Dow, an American electrician, publishes the following figures on the efficiency with which hydrogen is oxidised in air in the Dow air battery. This cell contains no depolarising agent, but depends entirely upon the oxidation of the nascent hydrogen by air to keep it from polarising. It is composed of zinc and carbon electrodes in a saturated solution of calcium bromide. The carbon used is very porous, and by capillary action holds some of the electrolyte within its pores, although its outer surface is largely exposed to air. The reaction that takes place on the zinc electrode is expressed by the equation $Zn + CaBr_2 + 2H_2O = ZnBr_2 + CaO_2H_2 + H_2$. The zinc bromide and calcium hydrate thus formed react on each other with the formation of zinc hydrate and the same amount of calcium bromide with which a start was made, $ZnBr_2 + CaO_2H_2 = ZnO_2H_2 + CaBr_2$. The result so far as total energy generated at the zinc electrode is concerned can, therefore, be expressed by the equation $Zn + 2H_2O = ZnO_2H_2 + H_2$. The H_2 would, however, when the circuit was closed, appear on the carbon electrode, where it would accumulate and polarise the cell unless oxidised. The reaction that takes place on the carbon electrode is simply the combustion of the hydrogen by the oxygen of the air, producing water. The original and final products may therefore be represented by the following simple equation: $Zn + O + H_2O = ZnO_2H_2$. By substituting the heat of combustion for the water and zinc hydrate we find that 82·68 heat units would be developed, which corresponds in this case to almost exactly 1·8 volt if all the energy appeared as electricity. Similarly, if all the energy was transformed into electricity in the same battery without access of air, according to the equation $Zn + 2H_2O = ZnO_2H_2 + H$, only ·3 volt would be produced. The 1·5 volt difference between the two cases is produced solely by the oxidation of the hydrogen. The actual voltage found in these air cells is 1·32, or 1·02 volt more than if no air had been present. Therefore, in this case $\frac{102}{180}$, or about 57 per cent., of the total energy contained in the hydrogen was converted into electricity. This result, showing five times the efficiency of our best steam-engines, at first appears very remarkable, but in this case nascent hydrogen was oxidised, while in the case of heat-engines the free hydrogen is burned. An experiment with a similar cell having two carbon electrodes and depending entirely on hydrogen gas and air for the production of its current gave less than one tenth of a volt E.M.F.

Measuring Hysteresis.—On April 26 we reported the paper read by Prof. Ewing before the Institution the previous evening on "A Magnetic Tester for Measuring Hysteresis in Iron." In the discussion which followed one of the other professors mentioned that the American Prof. Elihu Thomson had done something in the same line. The *Electrical World* of New York has just made the same discovery, and says: "It will doubtless interest Americans to learn that a very similar instrument was suggested and used by Prof. Elihu Thomson quite a number of years ago, and which in some respects appears to have been even an improvement on the Ewing form. As early as 1889 Prof. Thomson made some experiments with an instrument for measuring hysteresis which depended on driving sample discs of iron in a magnetic field by a small meter motor, and measuring the amount of a current required to be put through the meter, which thus became a measure of the torque exerted in the magnetic field. A speed counter was included in the instrument. The discs were stamped out by a standard punch, and a set of them were strung on a vertical shaft; the field in which the armature revolved was furnished by a definite current. He used the instrument for determining the hysteresis in different samples of iron as also in a modified way by taking the bundle of discs and winding on them a simple drum winding provided with a commutator, by which means he was able to drive the discs, which then became the armature core, between the poles of an electromagnet, the strength of which could be made less or greater; as in the other form the armature current was measured, giving a measure of the hysteresis or the total work done in revolving the bundle in the magnetic field. The friction error was fairly constant, and a correction had to be made accordingly. In the other form of apparatus in which the meter armature was driven by a current, the correction could easily be made by revolving the discs and shaft by a current passed through the meter armature while the field which magnetised the disc was removed, making readings at various speeds and noting the current required to drive the apparatus at these speeds; this current deducted from the total with the field on, at any given speed, would show at once the current required to do the work of rotating the discs—that is, of supplying the energy lost in hysteresis at various speeds, allowing for eddy-current effects. A modified form of the instrument has been used by the General Electric Company for some time and we believe is still in use by them for testing the samples of iron."

The New Central London Electric Railway.—Arrangements are being made for practically commencing the Central London Railway, for which three Acts of Parliament have been obtained. These Acts, passed in the course of the last three years, authorise the construction of an underground railway, running in a line almost straight from Shepherd's Bush to the open space in front of the Mansion House and the Royal Exchange, and thence to Liverpool-street, where, subject to arrangements being made with the Great Eastern Railway Company, it is proposed to construct a terminal station underneath their terminus. By the system of constructing underground lines so successfully illustrated in the electric railway running from the Monument to Stockwell, and by the line now in course of construction between the City and Waterloo, the new line will be carried out without the least disturbance of the streets or any peril to property. Its length will be 6½ miles, and there will be 14 stations. Starting with electrical generating works and a station at Shepherd's Bush, there will be another station at Queen's-road, and one at Holland-park. The next will be at Notting Hill-gate, another at Westbourne-terrace, and another at the Marble Arch. Running straight down Oxford-street, there will be stations at Bond-street, Oxford-circus, Tottenham Court-road, the British Museum, and Chancery-lane. The line is to run under the Holborn Viaduct, to Newgate-street, where there will be another station, and thence with a slight deviation—unless the alterations contemplated by the City authorities should first be carried out, in which case this curve will nearly disappear—into Cheapside. The next station will be at the Bank, and thence the line will run alongside the Royal Exchange into Broad-street and on to Liverpool-street, passing on its way under the Circle Railway. Throughout its length the line will be carried through the London clay. There will be two tunnels, similar to those in the City and Southwark electric railway, but of larger diameter. They will be pierced by the Greathead shield system on precisely the same method that is adopted on a gigantic scale for the Blackwall tunnel. There will be no opening of the streets. Property will be purchased in accordance with the parliamentary powers conferred for the stations at the various points indicated, and from these various properties the tunnels will be driven, while the traffic overhead will go on quite undisturbed. From the West-end to the City the two tunnels, one for the up line and one for the down, will run side by side. The engineers, however, are forbidden to go under any building, and in the narrow City streets there is not sufficient room to carry the two lines side by side. They are, therefore, to run along one above the other, the lower one going past Bow Church, Cheapside, at a depth of 80ft. below the surface of the roadway. Emerging in the open space in front of the Mansion House and the Royal Exchange, the new line is to bring about a remarkable London improvement. All Londoners know the crowded and dangerous condition of the streets just here, and nervous people well know the difficulty of crossing the roadway at any hour of the day. Arrangements have been made with the Corporation by which the company will be allowed to build their station underground in the middle of this space, on condition that they construct a spacious subway for pedestrians all round it. This subway will be 15ft. wide, and will be accessible by easy flights of steps from all the surrounding thoroughfares. Foot passengers will thus be able to avoid crossing the roads at this point. A person may start at the Mansion House, descend a few steps, cross the end of Cheapside, of Princes-street, Threadneedle-street, Cornhill, Lombard-street, and King William-street, back to the Mansion House in perfect safety, while from this subway he will also be able to pass down to the station of the City and Waterloo line, or to that of the Central London Railway, which is to have, in addition to the several entrances at the end of the converging thoroughfares, two broad flights of steps leading down from each side of the pavement immediately in front of the steps of the Royal Exchange. The ground at this point in the City, it need hardly be said, presents a wonderful tangle of pipes and drains and cables and wires, and for these also the new railway has undertaken to make ample provision. Beneath the subway for foot passengers will be another subway about three times as large as will be required for taking in all the underground pipes and so forth, and which may therefore be expected to obviate any further disturbance of the roadway for generations to come. The main features of the new line will be those of the City and Southwark railway, with such modifications and improvements as the experience gained by that undertaking has suggested. That line, it may be remembered, was originally intended for working by cable. Electricity was an afterthought.

THE THEORY OF ALTERNATING CURRENTS.—VI.

BY A.INST.E.E.

§ 18. **Capacity and Condensers.**—In § 16, impedance was defined as the sum of every form of obstruction met with in alternating-current circuits, and as the component, reactance, often includes a factor due to capacity, we shall now briefly explain capacity and condensers, and then consider the effects produced when condensers are present.

Capacity, as is well known, is the power of a body to hold a charge of electricity, and is measured by the quantity of electricity required to raise the potential of the body by unity. It follows from this definition that the potential, E, of a body charged with Q units of electricity is proportional to Q, or, algebraically,

$$E \propto Q,$$

and $\therefore Q = K \times E$, where K denotes the capacity.

Now, the capacity of a conductor is increased by bringing near to it another conductor which is separated from it by an insulating medium or dielectric, and any device which exhibits a rise of potential when an accumulation of a quantity of electricity has taken place is termed a condenser.

Standard condensers consist of a number of parallel plates of tinfoil or other conducting sheets, separated by very thin sheets of mica, the first, third, and fifth, etc., and the second, fourth, and sixth plates, etc.—that is, the alternate conducting plates—being connected together so as to form two series of plates, which are connected to two brass pieces or poles on the outside. These form the terminals of the condenser. One set of plates receives a quantity of positive electricity when charged, whilst the other set is charged with an equal quantity of negative electricity. The two terminals may be connected by a plug so as to short-circuit the condenser. Insulated cables have a certain amount of capacity, and practically form condensers. Concentric cables have considerable capacity, especially when of great length, consequently capacity may be a very important factor in alternating-current distribution, and should not be neglected.

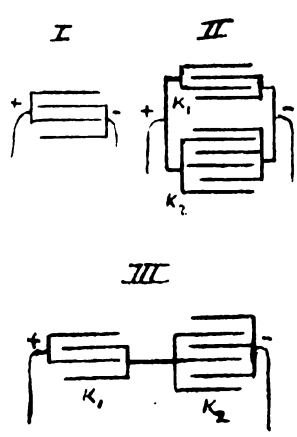

FIG. 12.

It will be well to notice here that a capacity of a condenser consisting of parallel plates, or in the case of a concentric cable of two conductors, is measured by the quantity of electricity on one plate or conductor when there is unit difference of potential between the plates or conductors. So far, the units referred to are C.G.S. units in the electrostatic system, whilst for practical purpose we require a unit of capacity corresponding to the volt, ampere, etc. This is termed the *farad*, and a condenser with a capacity of one *farad* requires one coulomb of electricity to produce a difference of potential between its poles equivalent to an E.M.F. of one volt. Since $Q = K E$,

$$K(\text{farads}) = \frac{Q\ (\text{coulombs})}{E\ (\text{volts})} = \frac{\text{charge on one pole}}{\text{D.P. between the poles}} = \text{a ratio},$$

and

$$1 \text{ farad} = \frac{1 \text{ coulomb}}{1 \text{ volt}} = \frac{10^{-1} \text{ G.G.S. unit}}{10^{8} \text{ G.G.S. units}} = \frac{1}{10^{9}},$$

or 10^{-9} C.G.S.

For practical purposes, however, the farad is too large, and the one-millionth part of a farad—*i.e.*, one *microfarad*—is the practical unit of capacity adopted by electrical engineers. A condenser with a capacity of one microfarad will thus require only one-millionth of a coulomb to charge it to one volt. Standard condensers of one-third microfarad capacity are used for testing purposes, since this value is approximately equal to the capacity of one nautical mile of Atlantic cable. Fig. 12 (1) shows the usual symbol for condensers, whilst (2) and (3) represent condensers connected "in parallel" and "in series" respectively.

In (2) and (3) it will be noticed that the two condensers connected have capacities K_1 and K_2, and it will be useful to remember that the capacity, K, of the whole arrangement is found as follows:

(1) *Parallel Arrangement*—

$$K = K_1 + K_2.$$

(2) *Series Arrangement*—

$$\frac{1}{K} = \frac{1}{K_1} + \frac{1}{K_2}; \text{ or } K = \frac{1}{\frac{1}{K_1} + \frac{1}{K_2}}.$$

It will be evident from the nature of a condenser that the capacity of such a device depends upon the size and geometrical form of the conductors, and upon the nature and thickness of the dielectric. We give here formulæ for determining the capacity of condensers in microfarads.

(1) Sphere:

$$K \text{ (microfarads)} = r/900{,}000 \text{ (radius} = r).$$

(2) Two concentric spheres:

$$K = k \frac{r\,r'}{r' - r} \Big/ 900{,}000 \left\{ \begin{matrix} \text{radii} = r \text{ and } r' \\ \text{specific inductive capacity} = k \end{matrix} \right\}.$$

(3) Cylinder:

$$K = \frac{l}{2 \log_e \frac{l}{r}} \times \frac{1}{900{,}000}; \text{ radius} = r, \text{ length} = l.$$

(4) Two concentric cylinders or concentric cable:

$$K = k \frac{l}{2 \log_e \frac{r^1}{r}} \times \frac{1}{900{,}000} \left\{ \begin{matrix} \text{internal radius} = r. \\ \text{external radius} = r^1. \end{matrix} \right.$$

(5) Parallel discs:

$$K = k \frac{A}{4 \pi t} \times \frac{1}{900{,}000} \left\{ \begin{matrix} A = \text{area}. \\ t = \text{thickness of dielectric}. \end{matrix} \right.$$

In all cases lengths are in centimetres, and k is the specific inductive capacity of the dielectric. It must also be noticed that

$$\log_e \frac{r^1}{r} = \left(\log_{10} \frac{r^1}{r} \right) \times 2{\cdot}3026.$$

An example taken from practice will simplify the method of determining the capacity of a condenser. The case we will consider is the concentric cable forming the trunk main connecting Deptford to the transformer sub-stations in the Metropolis. An idea of the cable may be gathered from Fig. 13, in which is given section of the cable, and,

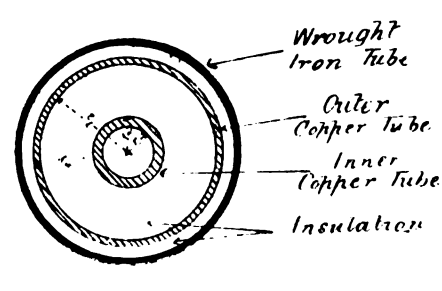

FIG. 13.

as we have already said, such a cable possesses capacity to a considerable degree.

The inner tube, A, and the outer tube, B, are copper

Digitized by Google

tubes, whilst C is a tube of sheet iron enclosing the cable, the three tubes being insulated from one another by an insulating material made of compressed brown paper and black wax, the specific inductive capacity of which is 3·37.

The values of r_1, r_2, r_3, and r_4 in Fig. 13 are as follows:

$r_1 = \cdot281$in. $\quad r_3 = \cdot922$in.
$r_2 = \cdot406$in. $\quad r_4 = \cdot969$in.

By applying the formula in (4) above, and using the data just given, we will calculate the value of the capacity of one mile length of this cable.

$$K\ (\text{microfarad}) = \frac{K \cdot l}{2 \log_e \frac{r^1}{r} \times 900{,}000}.$$

Since l = 1 mile = 160,931·5cm., K = 3·37;

$$\frac{r^1}{r} = \frac{\cdot922}{\cdot406} = 2{\cdot}27 \therefore \log_e \frac{r^1}{r} = (\log_{10} 2{\cdot}27) \times 2{\cdot}3026;$$

and $$K = \frac{3{\cdot}37 \times 160{,}931{\cdot}5}{2 \times 2{\cdot}3026\ (\log_{10} 2{\cdot}27) \times 900{,}000}$$ microfarad

= ·3675 microfarad.

§ 19. **Capacity and Reactance.**—With continuous currents a condenser practically opposes the flow of electricity when once charged, whilst it allows an alternating current to flow in and out, or, in other words, to pulsate backwards and forwards through its dielectric. It is obvious from the nature of condensers that so long as the current flowing to a condenser is positive, the charge on the condenser increases, so that the charge is greatest, and therefore the pressure between the plates is a maximum in the positive direction, just at the moment when the current is changing from + to −, that is, when the current is zero.

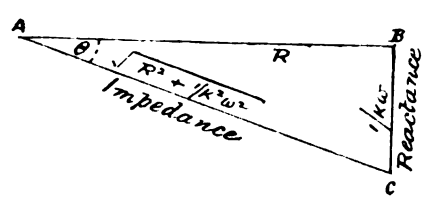

Fig. 14.

When the current changes its direction, the condenser begins to discharge itself, giving out a positive current, tending to drive the negative current back. In this way it reacts on the E.M.F. of the circuit tending to produce a *lead* in phase of a quarter of a period. Capacity-reactance, like inductance-reactance, is in quadrature with the current, but in effect it is equivalent to inductance-reactance of magnitude $1/K\omega$. Since capacity tends to produce a *lead*, whilst inductance tends to produce *lag*, capacity-reactance is written $-1/K\omega$. The impedance of a circuit containing a resistance R and a condenser of capacity K farads is $\sqrt{R^2 + 1/K^2\omega^2}$, as is readily seen from the construction of Fig. 14, in which A B represents R, and B C drawn below A B (since inductance-reactance was drawn above A B in Fig. 10, § 16), represents the capacity-reactance, and A C is the impedance as before.

As with inductance, $C = \frac{E}{\sqrt{R^2 + 1/K^2\omega^2}}$, and $\tan\theta = -\frac{BC}{AB} = -\frac{1}{K\omega R}$. As the treatment of the components—the power E.M.F. and reactive E.M.F.—of the impressed E.M.F. when capacity is combined with resistance, is similar to that given in the latter half of § 14, it is unnecessary to go over the ground again. There are, however, several interesting points in connection with capacity that it will be well to notice.

(1) The E.M.F. required *to overcome that* of the condenser is 90deg. *behind* the current, and its maximum value is $\frac{C}{K\omega}$.

(2) Since capacity-reactance $= -\frac{1}{K\omega}$, it may be looked upon as possessing an inductance $= -\frac{1}{K\omega^2}$, that is, a negative inductance, $-L = 1/K\omega^2$. This means that a condenser of capacity K has the power to annul the self-induction of a conductor in series with the condenser to the extent of $1/K\omega^2$ henrys. When $L\omega = 1/K\omega$, the reactance is zero, and as a result the current is in phase with the impressed E.M.F.

§ 20. **Circuits Containing Resistance, Inductance, and Capacity.**—It follows from (2) that $L\omega - \frac{1}{K\omega}$ = the resultant reactance for cases in which R, L, and K are in series. To solve the problem and find C, the equation $C = \frac{\text{impressed E.M.F.}}{\text{impedance}}$ becomes

$$C = \frac{E}{\sqrt{R^2 + (L\omega - 1/K\omega)^2}}.$$

The method of applying this formula will be readily understood by giving the graphical solution of the following problem, shown in Fig. 15, in which A is the alternator

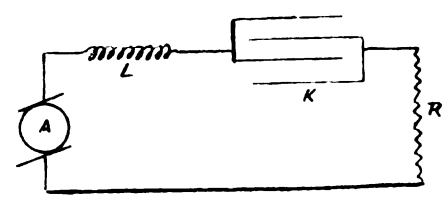

Fig. 15.

giving 2,000 volts effective at a frequency of 100, L is an inductance of ·4 henry, K = 10 microfarads, R = 100 ohms, and it is required to determine the current, C. In Fig. 16, let O B = 100 ohms to scale, O A = L ω, and O C = 1/K ω. Since the capacity-reactance, O C, is negative compared with the inductance-reactance, O A, the resultant reactance is found by making A D = O C—that is, O D is the resultant reactance, and D B = impedance to the same scale as O A, O C, and O B.

In this case $\omega = 2\pi \times 100 = 628{\cdot}3$, and $L\omega = 628{\cdot}3 \times \cdot4$ = 251·32 ohms, $1/K\omega = \frac{1}{\frac{10}{10^6} \times 628{\cdot}3} = \frac{10^5}{628{\cdot}3} = 159{\cdot}1$ ohms.

∴ D O = 251·3 − 159·1 = 92·2 ohms. From which we get D B = $\sqrt{(100)^2 + (92{\cdot}2)^2} = 133{\cdot}8$ nearly.

Or, algebraically,

$$C = \frac{E}{\sqrt{R^2 + (L\omega - 1/K\omega)^2}} = \frac{2{,}000}{\sqrt{(100)^2 + (251{\cdot}3 - 159{\cdot}1)^2}}$$

$$= \frac{2{,}000}{133{\cdot}8} = 15 \text{ amperes.}$$

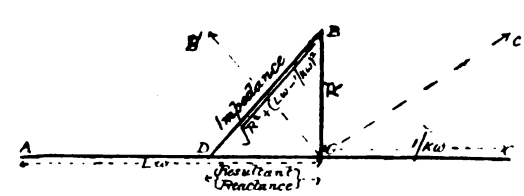

Fig. 16.

Another graphical solution is shown in Fig. 16, which is very useful in some cases. O C¹—shown dotted—is the resultant of O B and O C, and O B¹ is the resultant of O C¹ and O A. It will be noticed that O B¹ = D B.

THE QUALITIES OF MANGIN AND PARABOLIC MIRRORS.

We have received from M. Jean Rey, chief engineer to Messrs. Sautter, Harlé, et Cie., the following reply to the communication of Herr F. Nerz, published in our issue of June 14:

In your issue of June 14 was published a communication from M. Nerz, engineer to the Société Schuckert, relative to the qualities of Mangin and parabolic mirrors. M. Nerz

Digitized by Google

sets himself the task of refuting arguments put forward in a prior article of May 17, written in favour of Mangin mirrors.

I have no wish to prolong a discussion at the risk of fatiguing your readers, as I think that the simple geometrical considerations set forth in the article of May 17 were sufficiently clear and precise to enable anyone to easily form his own opinions. May I be allowed, however, to touch upon certain points in M. Nerz's letter.

Firstly, M. Nerz considers the experiments at Toulon as having demonstrated the superiority of parabolic mirrors. I assisted personally at the trials, and I fear that M. Nerz, who was not present, has been wrongly informed by his agents. The committee, which was composed entirely of naval officers, occupied itself solely with results obtained, without considering at all from whence came the apparatus employed. The question set by the Ministry of Marine was one of a purely technical nature, and was as follows: "Do parabolic mirrors possess superiority over Mangin mirrors?" The reply of the committee was unanimously, "No." This is a fact. M. Nerz has been also led into error on the subject of the provision of the particular Mangin mirrors experimented with. They were not constructed specially for the experiments: one of them, a mirror of 30cm. diameter, came from a lot of 20 projectors recently delivered, and the other, a mirror of 90cm. diameter, had been in use since 1889.

Secondly, I do not doubt the ability and skill with which parabolic mirrors are manufactured in the workshops of the Société Schuckert, nor do I doubt the progress achieved by the Société during the course of 10 years of work. I should like, however, simply to ask M. Nerz if he is prepared to undertake the delivery of parabolic mirrors, of 90cm. diameter, sufficiently exact in form to enable parallel rays coming from an infinite distance to cross one another after reflection within a sphere of 1mm. diameter? If I am well informed, I understand that Société Schuckert, in undertaking a recent supply of mirrors for a neighbouring Power, would not submit to a specification which laid down a dimension smaller than 7mm. for the diameter of the sphere alluded to.

Thirdly, I did not expect that it would be claimed as one of the qualities of the parabolic mirror that it possesses a solidity greater than that of the Mangin. It is of little consequence if a Mangin mirror be thin at its centre. The form of the Mangin mirror is one which offers the most even resistance to strains applied, whereas the parabolic mirror can with difficulty be kept from deformity without being most rigidly mounted, and in such a manner as must of necessity cause most dangerous stresses to be set up by over-heating. M. Nerz asks what experience we are able to oppose to his own. The reply is easy, for Messrs. Sautter, Harlé, et Cie. have delivered up to the present more than 3,000 Mangin mirrors. They do not pretend that none of these have been broken by accident, but, as far as they know, none of them have perished from over-heating or from the concussion of neighbouring guns. Nor have any of them perished from indeterminate causes, as has been the case with 50 per cent. of the parabolic mirrors comparatively recently installed in a fortress not 100 miles from the shores of France. At Toulon I witnessed the refusal of M. Nerz's agents to comply with the request of officers who wished to try a parabolic mirror of 38cm. focal length with a current of over 100 amperes; they feared a dangerous over-heating. M. Nerz's principal weapon of offence in attacking the Mangin mirror has hitherto been the short focal length which can be employed with the parabolic mirror. This weapon he has apparently discarded, or why should the Société Schuckert have abandoned the types of very short focal length, such as those of 90cm. diameter with a focal length of 31cm., which they were constructing some few years ago?

Finally, M. Nerz attaches great importance to the absorption due to the thickness of the glass towards the edges of the Mangin mirror, and he refers to a discrepancy between the figures quoted by M. Blondel in his "Theory" and those recently published by Messrs. Sautter, Harlé, et Cie. I am happy to be able to set his mind at rest on this point by informing him that the coefficient of absorption quoted by M. Blondel, and which was the result of measurements made by me in 1889, has been found from more accurate experiments which I conducted in 1894 to be too high for perfectly-polished glass of the kind from which our Mangin mirrors are made. The actual absorption does not reach one-third of the amount formerly arrived at. This difference has, however, little or no importance when considering the efficiency of the whole mirror, as this will vary scarcely 2 per cent. whichever coefficient be taken. Such a percentage of variation is less than that of the errors made in observation. I have, moreover, actually compared the total absorption of a Mangin mirror with that of a perfectly-polished parabolic mirror of the same diameter, and though contrary to the published statements of M. Nerz, I find that the losses of flux are sensibly the same for both types of reflector.

These are, Sir, the several points which I would wish to lay before such of your readers as may be interested in projectors. It is to be regretted, however, that M. Nerz has thought fit to accuse us of ignoring the teachings of science and of technical experience. We do not do him the same injury, and are quite prepared to continue this discussion, from which he will be able to more seriously study the properties of the Mangin mirror.

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

The series of articles of which this is the first, is intended for readers having some experience in practical electrical work, but lacking the advantage of training in theory and mathematics. It is intended to familiarise such with the method of representing facts by means of curves, and with the analysis of curves embodying the results of their own or other men's work: we might say, briefly, with the writing and reading of curves.

With this specific object in view no apology will be needed for treating the subject in an elementary manner, and the general lines followed will be simple and easy. It is hoped thus to enable the non-mathematical reader to handle what may be called a part of electrical graphics familiarly, and with a clear and thorough understanding of what he is doing. It must still be admitted that the man who has even a smattering of mathematics has an advantage over him who has not.

The fundamental principle of all curve plotting is in that all simple quantities (known as "scalar quantities") can be adequately represented by the length of a line. Let us take a somewhat absurd but simple illustration. A man is in the habit of ordering goods regularly from some dealer. The goods are of one sort only, and sold in the same way always—say, sugar sold by weight. At last the customer says he will not be bothered to write the order in full each week—the dealer is to understand that a line 1in. long means a pound of sugar, and henceforth he will send postcards with merely a line to represent the amount of sugar. This example may seem puerile, but it is not unnecessary thoroughly to grasp that if that customer sends a postcard with a line 3⅞in. long drawn on it the dealer knows *exactly* what is wanted. The length of a line may be made to adequately represent a quantity. All that is necessary is to arrive at some stated agreement as to what quantity a certain length of line shall mean. This length and this quantity are then our units. It is troublesome to have to measure the length of irregular lines and curved lines, and it is therefore the practice to confine oneself to straight lines for the representation of quantities. The mere possibility of thus even adequately representing a quantity by a length would be of little use, however. It is not until one wishes to represent two connected quantities at one time that the value of this method is apparent.

Let us then see how time and money when connected may be thus at once represented. Taking any point as a datum point, let distance from it—*i.e.*, length—along one straight line mean time; and in order to show money as distinct from, and yet connected with time, let distance from the same point but in a direction at right angles to the other mean money—say, income.

Digitized by Google

We have taken two straight lines at right angles as the directions along which we mean to measure for convenience, but, as we shall see later on, it is immaterial what two directions are taken; it cannot be too frequently and clearly insisted upon that the only thing needed is length—everything else is a convenience in method.

With so much agreed upon, it is possible to represent exactly the fluctuations in a man's income. We have but to choose our scale and draw the two straight lines as directions along which we mean to measure. The datum point we will call O, and the two lines along which our measurements are taken O X and O Y, Fig. 1.

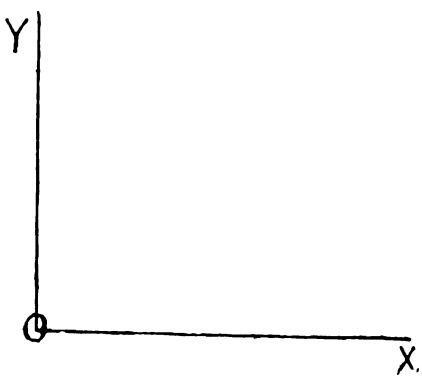

FIG. 1.

These lines, be it remembered, are only *directions*, and purely arbitrary; our convention is to draw them at right angles for convenience, and since they are directions, the actual ink-mark, O X, is only part of an imaginary infinite line. When, therefore, we speak of the direction O X, we may mean to the right or left of O, and possibly right off the paper which contains the actual length, O X.

Along this direction O X we will take length to mean time, and along O Y length shall mean income.

The point O is our datum point from which we have arranged to make our measurements both of time and income. It must, therefore, have a significance in both quantities. A simple meaning in income which we may attach to that point is that of no income at all, so that no distance from O in the direction of O Y means no income. But what are we to do at O with time? If we say let it be when time is O, we must explain what we mean: time = *o* can really have but one meaning—viz., the point of time from which we begin to count. With reference to this particular man, some may urge that in his case time = *o* at the instant of his birth; but does it? To him it does, because he counts existence and time from that point, but there was a time prior to that. Obviously, then, $t = o$ at whatever instant we may choose as that at which we will begin to take observations.

In this man's case we will begin to note his income when he is 16 years old: on the instant of his commencing his seventeenth year of existence.

Let us again state what is our convention, and then choose a scale.

The point O is chosen to mean: first, the point in the man's life—*i.e.*, that point of time—at which he entered on his seventeenth year; second, that point in his income at which his income was nothing; lengths along O X are to mean time, and lengths along O Y to mean income.

Let $\frac{1}{4}$in. along O X mean a month, and 2cm. along O Y mean 5s. a week. If we now measure 2cm. along O Y, Fig. 2, and put a dot, P, to mark the point, that length, 2cm., means 5s. a week; but if this dot is a point connecting income and time—as it must be if it be a point on our curve—what connection has it with time? Time we have agreed to measure from O in the direction O X. Well, our dot, P, has no distance from O in that direction, therefore no time has elapsed. From this we infer that when our young man had completed his sixteenth year (for that is the point of time at O) his income was 5s. a week; in other words, he started at 5s. a week on his sixteenth birthday. Say we are told that at the end of three months he was getting 10s.; to represent this we must find a point at a distance of $\frac{3}{4}$in. from O along O X, and 4cm. from O along O Y. The point *a* is the first and the point 1 the second; but we want *one* point with the properties of these *two* in the above-named respects. This we have in the point P', Fig. 2. For see, the distance P' to 1 is $\frac{3}{4}$in., and it is in the direction O X, and the direction P' *a* is 4cm. from O in the direction O Y. P' is therefore a point on our curve; and if we handed that simple diagram, Fig. 2, with the statement given above respecting O, O X, O Y, and our scale, to a person, that person with a steel rule could tell us as certainly as if we had informed him in so many

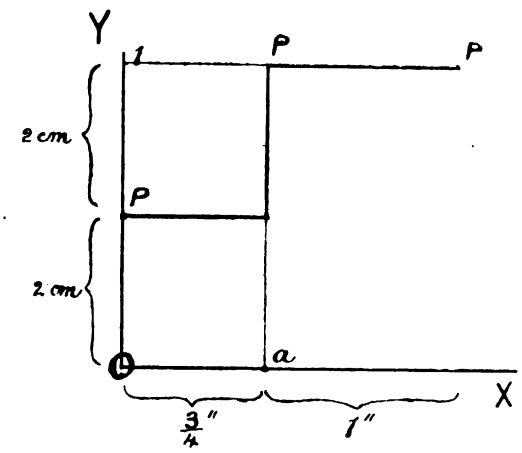

FIG. 2.

words, that the young man started on his sixteenth birthday with 5s. a week and received a 5s. rise in three months. If this line be continued to P" for a length of 1in., he will know that for the next four months he received the same income; but there our curve stops, and beyond that point of time—viz., seven months from the start—gives us no information.

(To be continued.)

CALORIFIC VALUE OF REFUSE.

At the late annual meeting of Municipal Engineers at Halifax a paper was read by Messrs. T. S. McCallum and W. Naylor, the latter part of which gave the results of Mr. Naylor's experiments on the calorific value of the refuse destroyed. These results in some measure differ considerably from those recorded by other experimenters; and as the subject is of importance both to municipalities and to electrical engineers we give that part of the paper relating to this question, as follows:

The trials at the works were made with the help of Mr. McCallum and other assistants on Friday, May 24, for machinery and refuse destructors, and Tuesday, the 28th, for raw sewage and effluent only. The raw sewage was sampled every quarter of an hour from 10 a.m. until 2 p.m. The quantity of sewage treated was 42,250 gallons, to which was added 53lb. of precipitant (ferozone), or 8·8 grains per gallon. This was allowed to settle until 6 p.m. The filters were then put into operation, and were running from 6 o'clock to 6.50, samples also being drawn every 10 minutes. At 6.50 the head of water on the filter had fallen 6·5in., which is equivalent to 30·6 gallons per square yard per 50 minutes, or 880·8 gallons per square yard per 24 hours. The results of this treatment are set out in Table A. This shows that the percentage of reduction brought about is—

	Per cent.
For total solids	16·2
,, albumenoid ammonia	81·5
,, oxygen absorbed	87·8

The composition of the precipitant was:

	Per cent.
Silica	5·75
Moisture (free)	20·09
Ditto (fixed)	12·31
Sulphate of alumina	38·23
Ferrous sulphate	4·03
Lime, magnesia, etc.	19·59
	100·00

The actual amount of sludge produced was not calculated, as this is very variable, according to the quantity of precipitant used and the length of time it has been standing. Its composition, guessed, however, was:

Boilers and Destructors.

The trial of boilers and destructors was carried out on the lines suggested in the report of Mr. Michael Longridge, M.I.C.E., for 1887 to the Engine, Boiler, and Employers' Liability Insurance Company. Four furnaces were working from 11.45 a.m. to 5 p.m., or 5¼ hours. The start was made with the hoppers, furnaces, boiler pressure, and water-line at points noted, at which points also the trial was finished. The amount of refuse burned was weighed out in 98lb. lots, and amounted to 9,996lb., or 4·46 tons. The ash and clinker weighed out from this was 4,638lb. (2·07 tons), or 46 per cent. of the input. The self-evident incombustible matter—such as tin cans, etc.—was sorted out from the refuse and not weighed in; but it averages, I am informed, all the year round about 2·2 per cent. of the carted refuse. The water evaporated from this was 3,998lb., or ·40lb. of water per pound of refuse. This was evaporated straight from the filter-beds at a temperature of 58deg. F. Calculating the water evaporated from and at 212deg. F., it would amount to ·46lb. of water per pound of refuse. Now this result appears very low, especially side by side with trials of refuse destructors which have recently been published claiming evaporation of about 2lb. of water per pound of refuse, and it was really this very low result at a preliminary trial which prompted this more careful trial and investigation. The analysis of the refuse as sampled from 102 tins weighed out was:

	Per cent.
Moisture, dried at 212deg. F.	25·3
Volatile matter	28·2
Ash	46·5
	100·0

A sample of the refuse dried contained:	Per cent.
Combustible carbon	11·2
,, hydrogen	·12

The calorific value of the refuse dried, therefore, deducted from this analysis is 1,693 (taking the calorific value of carbon at 14,545 and hydrogen at 53,337), or about one-seventh of good steam coal. Tested practically with a calorimeter, the carbon value of the refuse was so low that combustion even in oxygen mixture was impossible, but mixed with a weighed quantity of coal, the calorific value of which was previously determined and afterwards deducted, the calorific value of the waste was 1,702. It was preferred, however, to take the theoretical figure, as the difference between that and the practical test is represented only by less than one-tenth of a degree on the thermometer, to read which was impossible with the thermometer used.

Determination of calorific value of coal (two grammes coal and 1,934 grammes water taken):

	Deg. F.
Original temperature of water	62·0
Final	74·5
Difference	12·5
Add 10 per cent. for heat retained by copper cylinder	1·25
Calorific value in B.T. units – 13,296·25	13·75

Determination of calorific value of refuse (two grammes coal, two grammes refuse, and 1,934 grammes water taken):

	Deg. F.
Original temperature of water	63·0
Final	77·1
Difference	14·1
Add 10 per cent., as before	1·41
	15·51

Calorific value of total	14,998
,, ,, coal only	13,296
,, ,, refuse	1,702

As the refuse, however, is here calculated dry, and it really contained 25 per cent. of moisture, its calorific value is ·75 (1,693) = 1,269; but even this is not available, for the 25 per cent. of moisture must be evaporated from the refuse representing 1,269 units, at the expense of its own inherent heat, before any work can be got out of it. The temperature of the refuse as fed in was 58deg. F., and the thermal units required to evaporate ·25lb. of water from 58deg. F. at atmospheric pressure $= \frac{1,146-58}{4} = 272$ thermal units. This brings us now to the real value of the refuse—viz., 997 (1,269 – 272) thermal units per pound wet. Let us now look how these 997 units of heat are disposed of.

Heat Lost by Drawn Clinker.—One pound of refuse produced ·46lb. ash and clinker. This clinker was allowed to lie, however, in the ashpits until it reached a temperature of only 500deg. F., and was then wheeled out. The heat given off, therefore, in falling to this temperature would enter the furnaces with the draught. ·46lb. × ·17 (specific heat of clinker) × 442 (500 – 58, number of degrees raised) = 34·5 thermal units.

Heat Lost by Unburnt Carbon in Clinker.—The dry clinker contained 1·8 per cent. of unburnt carbon, which is equivalent to ·008lb. per pound of refuse burnt. ·008 × 14,545 = 116·37 thermal units, also lost.

Heat Lost by Heating of Products of Combustion, Excess Air, and Superheated Vapour.—Samples of the gases drawn from the flues consisted on the average of:

	Per cent.
Carbonic anhydride	4·7
Oxygen	14·5
Nitrogen	80·8
Carbon monoxide	0·0
	100·0

Or, since air contains 21 per cent. oxygen and 79 per cent. nitrogen, we may write it down:

	Per cent.	
Carbonic anhydride	4·7	Products of combustion.
Nitrogen	26·3	
Excess air	69·0	

This result, owing to the nature of the refuse burnt, is very much different to what takes place in a good coal furnace, where the products of combustion are about double the above and the air in excess about half. Now, this excess of air, as well as the products of combustion, must be heated to the exit temperature of the flue, which, as recorded by the thermometer, averaged 356deg. F.

The weight of carbonic anhydride per pound of refuse equals (3·66) × ·075, number of pounds carbon burnt = ·2745lb. $\frac{\cdot2745}{\cdot122} = 2·22$ cubic feet, and since the composition of the gases shows the carbonic anhydride to be 4·7 per cent., the total volume of gases per pound of refuse will be $\frac{2·22 \times 100}{4·7} = 47·2$ cubic feet, and this 47·2 cubic feet will be made up as follows:

	Cubic feet.		Weight per lb.	lb.
Carbonic anhydride	2·22,	or refuse =	2·22 (·1222) =	·2708
Nitrogen	12·4,	,, =	12·4 (·078) =	·9672
Air	32·5,	,, =	32·5 (·081) =	2·6325
Total				3·87.5

To the weight of these gases must also be added that of steam formed by the combustion of the hydrogen in the refuse, which was ·12 per cent. dry. The actual weight would therefore be ·75 (·12) = ·09 per cent. = ·0009 per pound hydrogen, = 9 (·009) = ·008 steam. The 25 per cent. of water in the refuse also, existing as moisture, must be added to the gases, which, of course, as steam would have the same weight—

Digitized by Google

viz., ·25lb.; and, lastly, the aqueous vapour in the atmosphere, which amounted to ·04lb. in the 48·2 cubic feet of air drawn through per pound of refuse. The weight of aqueous vapour in this 48·2 cubic feet of air is corrected for temperature and pressure at the time of the trial.

$$\frac{48\cdot2 \times 29\cdot9 \times (1 + 00\cdot2 \times 76)}{29\cdot02 \text{ actual pressure} - \text{tension aqueous vapour at } 58^\circ \text{ F.} = 52\cdot2.}$$

$$52\cdot2 \times \cdot00077 = \cdot04.$$

From the above calculations the following Table B concerning the heat carried away by the exit gases can be drawn up:

In addition, however, to the calorific value of the refuse calculated as sensible, the heat contained in the entering air, vapour, and fuel must also be added to that which is sensible in the refuse. This is as follows: fuel, 1lb. × ·2 (specific heat) × 26 (number of degrees above zero) = 5 units; air, 2·632lb. × ·238 (specific heat) × 26 = 16·2 units; aqueous vapour, ·04lb. × ·481 (specific heat) × 26 = ·5 unit.

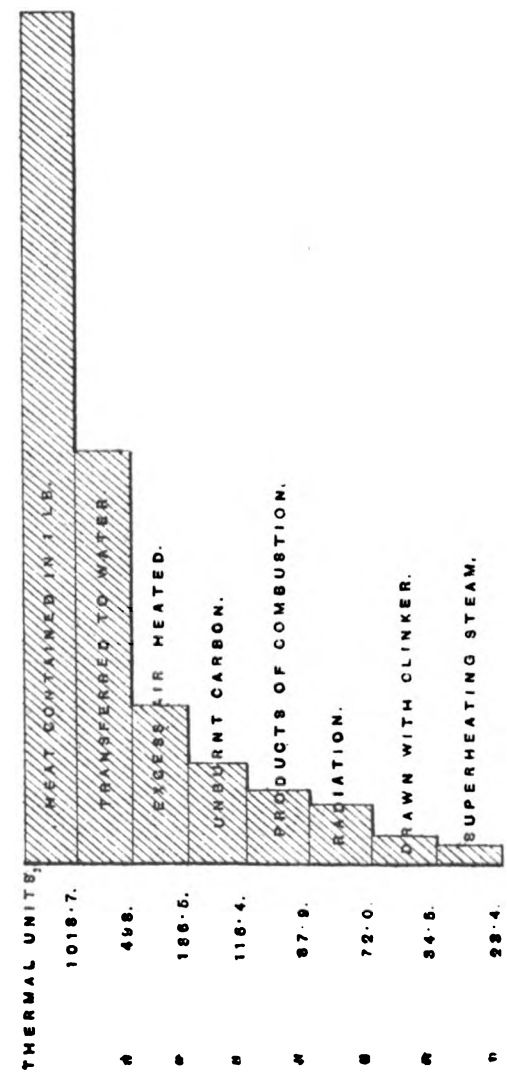
SLUDGE-PRESSING.

The steam generated was used for sludge-pressing, but it was impossible to run the compressor at a uniform speed throughout



Royton Sewage Depot.—Heat-Disposal Diagram, 1lb. Refuse.

the 5¼ hours from the very nature of the work. But when the condition of the rams permitted it, the compressor was run at its normal speed of 130 revolutions right through the receiver at 100lb. into the rams. When this was not possible, the ram was shut off from the receiver and the latter run up to 100lb. and then opened on to the rams, the falls in pressure being noted as well as the temperatures of the receiver. By this means the amount of air used for sludge pressing could be calculated. The amount of dry sludge turned out by each press averaged 2,025lb., or 18·9cwt., at each pressing, which is equivalent to 150·67cwt. wet, the wet sludge containing 88 per cent. water. To compress this the compressor was running at 130 revolutions right through the receiver at 100lb. for 59 minutes, delivering 257·4 cubic feet of air at 100lb. pressure and 225deg. F. into the rams. This at 58deg. F. measures only 194·6 cubic feet, the reduction on cooling being 24·3 per cent., though, of course, some compression in the ram may have taken place before the whole mass of air had cooled. To this must now be added 62·3 cubic feet turned in from the receiver (in 18·8 minutes), making a total of 256·9 cubic feet for two presses, or 135·9 cubic feet of air required per ton of sludge dry, which is equal to a mean pressure in the ram of 45·51b. From the diagram it will be seen that the compressor was indicating 7·1 h.p. in the steam-cylinder loaded, and 1·49 h.p. light; but the effective horse-power here is not the difference

Digitized by Google

between the one and the other, for as the air is not cooled during compression, owing largely to the leakage of hot air, a certain amount of work is afterwards lost when it becomes cooled and the pressure falls in the ram. The diagram which would have been made in the air-cylinder had the air been thoroughly cooled, is represented by the dotted isothermal curve, or, perhaps, it might be termed the cold-air curve. The actual air delivered per stroke at 100lb. and 225deg. F. was only ·02333 cubic feet. It will also be noted here that even the air which was compressed leaked back again from the receiver to some extent, owing to the check-valve being out of repair. This was noted at a preliminary run a few days before this recorded trial and pointed out to the Board, who reported to the authors that the valve had been repaired. It was only after the actual trial had started that the diagram disclosed the fact that it had not been effectually remedied. The curve which the back-pressure line should take is shown by the lower dotted line, allowing ¼in. clearance. An allowance has been made for this leakage in calculating the actual amount of air admitted to the rams, though no deduction was made for the difference in temperature between the discharged air and the air which leaked back.

It would be manifestly unfair, owing to leakage, to refer to the indicated horse-power per hour per ton of wet sludge pressed, or, what is the same thing, per cubic foot of air delivered to the rams at 100lb., for although the slipping air would react on the back stroke, a given volume of slipping air at a given pressure represents really more work than the same volume at the same pressure on the forward stroke, owing to the fall in temperature after delivery. Again, the relation between the light load and working load will be the same whether leakage is going on or not, so that in case leakage does exist, the indicated horse-power per cubic foot delivered will be much higher than in the absence of leakage. Since the air-compressor was not running either uniformly or continually during the 5¼ hours' trial, the quantity of steam used per stroke of the piston could not be measured by the water evaporated. The diagrams, however, show it to be 41·74lb. per hour per indicated horse-power. To this must be added 1 per cent. condensed in the 80ft. length of steam-pipe, including five bends, as recorded by tests made with a globe calorimeter = 42·15lb. The same instrument recorded little or no priming in the boiler, which could only be expected, considering the comparatively low pressure—70lb.—slow consumption, and large dome. To the 42·15lb. must be added 10 per cent. for cylinder condensation, which brings the consumption to 46·36lb. Now, since the boiler evaporation was $\frac{\cdot 4 \times 9996}{5\cdot 25}$ = 639·6lb. per hour, the indicated horse-power possible, had the compressor been working continuously, was 13·7, or 3·4 horse-power per hour per cell. The diagrams also show that the actual work performed on the piston was 224,598 foot-pounds, which are equivalent to 290·9 units of heat per minute. But to do this work the steam consumed per minute was 5·48lb., containing 6,295 units of heat, the difference between the two—viz., 6,004—being lost by radiation, or carried away by the exhaust.

The balance-sheet may now be continued, to show how the 498 units of heat entered as transferred to water are disposed of finally:

Dr.	Thermal units.
Transferred to water from refuse, etc.	498
	498

Cr.	Thermal units.
Lost by condensation in steam-pipes	4·98
Carried away by exhaust steam and radiation	470·0
Converted into work on piston	23·1
	497·98

Of the 23·1 units of heat really converted into work on the piston, 4·8, or 21 per cent., are taken up by the weight of moving parts; and, again, 5·6 units, or 24·3 per cent., are afterwards lost on the cooling of the compressed air, leaving only 12·7 thermal units, or 1·2 per cent., of the refuse value in hand contained as energy in cold air at 100lb. pressure. The accompanying diagrams represent the foregoing analysis.

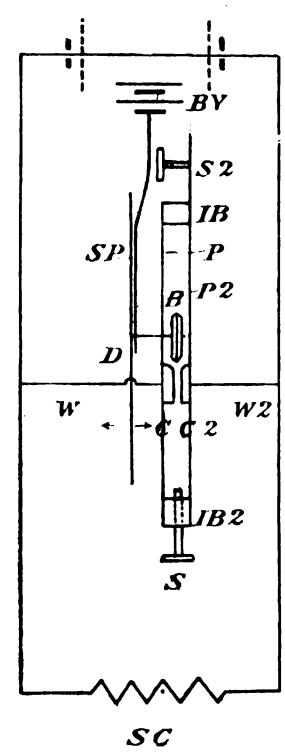
In conclusion, it is desirable to state that this trial is not by any means submitted as a model result, but simply to show what is at present going on at Royton. The authors do not for a moment suggest that the arrangements as described should be followed out by other engineers designing plant for the same purpose. If the results show anything at all they show that the idea of burning town refuse at any sort of profit is erroneous. It cannot be imagined that refuse which gives on evaporation anything less than 2lb. or 3lb. of water per pound of refuse would pay for carting. And what sort of refuse must that be? Certainly not the kind found in Lancashire; and, if not there, where can it be found? In burning town refuse one labours under the disadvantages of: (1) a large percentage of moisture in the refuse; (2) the necessity of heating a large percentage of air in excess in order to get it to burn at all; (3) the loss of considerable heat in the abnormal quantity of ash produced.

The above results point to a calorific value of about 4,000 thermal units to be possessed by town refuse containing the moisture which it usually does to bring about an evaporation of 2lb. of water, and any refuse containing this is practically only half-burnt coal. If any economies are to be effected in the future in the utilisation of town's refuse, the points towards which attention might be profitably concentrated are, as shown by the results here recorded: (1) Reduction of loss of heat owing to evaporation of moisture contained in the refuse. Such reduction will probably be brought about by the utilisation of the exit gases for drying the refuse primarily. (2) Reduction of loss incurred by the heating of excess air. There is certainly no known probability of burning the refuse with a smaller quantity of air, but another mode of economical working is open—viz., that of abstracting from the excess air by means of economisers some portion of that heat which at present it carries away.

But apart from the actual burning of the refuse, greater economies may surely be effected at sewage-disposal works by the adoption of condensing steam-engines, considering the low pressures used and the abundance of cooling water, and again by the retention of the partially-exhausted air, which is at present blown to waste out of the sludge-rams.

TELEPHONE TRANSMITTER.

In this transmitter the direction of the current is changed, as well as varied in strength, without breaking the battery circuit. Will readers interested kindly give their experiences with regard to circuits using this or similar transmitters? Referring to the diagram, D is the section of the diaphragm, S P is a spring connected to one pole of the battery, BY, and fitted to press on D at the centre. S P also carries a carbon or metal bevelled edge button, B, on a stalk, through which the movements of D in the direction of the arrows is transmitted to B. B may be turned round and new surfaces presented to the contacts. P and P_2 are two stiff plates, insulated from one another, and fixed to the insulating blocks, I B and I B_2.



C and C_2 are two carbon contacts, shaped as shown, and electrically connected to the other pole of the battery, BY, as shown. S is a screw by which the contacts, C and C_2, may be made to approach the button B vertically, and S_2 is a screw by which they may be adjusted horizontally. Usually the contacts, C and C_2, are adjusted to make equal contact with B, so that practically equal currents pass through the wires, W and W_2. The vibration of the diaphragm will alter the relative resistances between the contacts C, B, and C_2, and as a result the current through the shunt circuit, S C, will vary in direction as well as in quantity. The circuit through S C may include the receiver of the distant station or the primary of the local transformer. The cells may be arranged in the positions shown by the dotted lines.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

ELECTRICAL GRAPHICS.

The question of the mathematical treatment of physical problems has been for years an obstacle in the way of many men not blessed with a good mathematical knowledge. It is surprising that many electrical problems, capable of easy solution by simple proportion, should have called forth such a show of integral calculus and differential equations. The practical result has been that certain subjects are practically closed books to many men fully capable of understanding every practical fact about them. To state an example: a certain gentleman designs, say, a wattmeter, and calculates to a tenth per cent. by mathematics the accuracy of its readings and the general truthfulness of his most excellent device; yet the said wattmeter has the audacity to lie persistently behind his back, and turns out to have a large error in certain circuits in spite of the mathematical calculations. On the other hand, it will be rightly urged that the higher mathematics have been of inestimable service in the submarine cable work, and, indeed, in lighting and transmission work; though, as we say, the vast mass of it can be comprehended by those having a moderate mathematical training.

To state the facts concisely, the mathematical man without practice is a drug on the market, while the practical man without a fair knowledge of mathematics is seriously handicapped in his investigation work. It is practically impossible for a business man who has forgotten his elementary algebra, trigonometry, etc., to take up the study of the integral and differential calculus with profit to himself. There remains to him the system of reasoning by the aid of graphic construction and curves. This branch of study so developed and taught at the City and Guilds Institution, is essentially a practical man's tool. A mechanical engineer versed in indicator diagram work and Zeuner's valve diagram will readily pick up the essentials. The advantages of the plotting of curves to record the qualities of dynamos and alternators, etc., has been proved by the universal adoption of the methods in all electrical shops. In fact, this method of curve analysis may be considered to have the following advantages. It forms a ready means of calibrating measuring instruments of all kinds, as it enables faulty readings to be corrected. When used in such cases the error of the instrument can be obtained easily from the curves, and errors in the principle of construction shown. Again, for ascertaining the magnetic properties of iron, the method of plotting the induction and magneto-motive force is the only practical method of gauging minutely the quality of the samples. Even when wattmeter readings are taken to ascertain the hysteresis loss in the iron, the values for different inductions should be plotted to eliminate faulty determinations. In dynamo design, and kindred problems, the analysis by means of curves affords the only sight method in the practical determination of the qualities of the machine, and as such appeals with great force to all those engaged in the industry. The way in which the losses of an armature due to hysteresis

Digitized by Google

can be divided from those due to eddy currents is one example of this, and the man taking the subject up will be surprised at the facility offered for superimposing the various effects on one diagram.

We feel, however, that a large proportion of the young men in the profession are not in touch with these simple methods of avoiding higher mathematics. This is being overcome by the spread of technical schools; but many older members of the profession will also, we believe, read with interest the series of articles on this subject which commences in our current number.

COST OF POWER.

A letter from Prof. G. Forbes in our correspondence column raises many points of interest, and we should be glad if the information given in it could be supplemented by more figures. Prof. Forbes states that the aluminium works at Niagara are only charged for their electric energy at the rate of one-eighth of a penny per kilowatt-hour. We assume that the Niagara Falls Power Company expect to make a profit at this figure, but the capital charges alone appear to us to prohibit this. For a well-designed central station in England the first cost per kilowatt output rarely, if ever, has fallen below fifty pounds, even when fairly large units are employed. The alternators at Niagara are of larger output than any in the stations referred to, but the weight per kilowatt as obtained from Prof. Forbes's paper before the Institution of Electrical Engineers is not much less. Again, the large first cost of the works, including the tunnel, would keep up the cost per unit. So, assuming that at Niagara the first cost per kilowatt was as low as thirty pounds, and that the aluminium works took current continuously throughout the year, even then, owing to fluctuations in the resistance, in the pressure, and to periods of recharging, it is not probable that a total of more than seven thousand units could be supplied by one kilowatt of generating machinery. The income at one-eighth of a penny per unit would be $\frac{7,000}{8}$ = 875d. = £3. 12s. 11d. This shows a return of only just over 11 per cent. on the capital outlay of thirty pounds. We should expect this to be all absorbed in works charges, such as labour, repairs, oil, etc., and perhaps depreciation might claim a small surplus. Our assumptions as to load certainly are on the right side, but we should be glad if any errors in the other assumptions can be pointed out.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard.

COST OF POWER.

SIR,—You speak of ⅜d. per kilowatt-hour at Frankfort, and 1½d. at the Isar Works, as being an unprecedently low price for electricity. The price at which the Niagara Falls Power Company supply continuous current to the aluminium works at their required voltage is ⅛d. per kilowatt-hour.—Yours, etc., GEORGE FORBES.

London, W., June 28, 1895.

TRAMWAYS INSTITUTE.

SIR,—Should you find it convenient, I should feel obliged if you would kindly correct the statement which I am reported in your valuable paper to have made at the discussion referring to the different methods of mechanical traction for tramways, which is not quite correctly reported. My statement was that "*steam*" *was the prime motive power*, without which no other secondary motive power for tramway traction (whether electrical, compressed air, gas, or cable traction was used) could be produced. Whether the one or other method could be more advantageously used, depended mostly on local conditions and the traffic requirements. But if a line was to be worked *under the most difficult conditions* as to its position and requirements, that steam, as the most powerful analogue to our railways, would prove to its best advantage. Besides, *steam* could be worked as *economically* as any other kind of traction.—Yours, etc., H. CONRADI.

London, N.W., July 1, 1895.

ELECTRIC METER TRIALS IN PARIS.

SIR,—May we ask you to insert a correction of an error made by you in your last week's issue referring to the Aron meter? You state that the failures in this instrument have been to the extent of 15 per cent. If, however, you will refer to *Bulletin* No. 3 you will find that the failures are stated to have been *15 per mil*, or only 1½ per cent., which we may say is in accordance with our own experience in England, where we find that, amongst the great number of Aron meters in daily use, not more than 1 or 2 per cent. are considered incorrect. We shall thank you if you will kindly give this correction some prominence, as an error of this kind might be very prejudicial to an instrument at present in use all over the world.—Yours faithfully,

THE GENERAL ELECTRIC COMPANY, LIMITED,
(G. Binswanger, Director).

London, E.C., July 2, 1895.

THE TRAMWAYS INSTITUTE DINNER.

The eighth annual dinner of this institute was held at the Holborn Restaurant on Thursday week. Mr. W. J. Carruthers Wain, the president of the institute, was in the chair, and a large number of tramway men were present. It was noteworthy that so few electrical engineers were present, but we predict that year by year the proportion representing electrical undertakings will rapidly increase. After an excellent dinner, the enjoyment of which was only marred by the heat, the long toast list was attacked with surprising vigour. Mr. John Waugh, C.C., proposed "The Houses of Parliament," to which Mr. L. Atherley-Jones, M.P., responded at length. As Mr. Ebbe Smith was not present to take up his duties, another of that extensive guild, Mr. Holroyd Smith, stepped into the breach and proposed "The Local Authorities." He had many good opinions of the gentlemen constituting the local authorities, and welcomed the increasing influence which they had over tramway work. Mr. Smith had fought with these authorities in the old days, but now was ready to work with them to any extent. It came as a rough shock to those not thoroughly versed in the history of tramway work to be immediately afterwards assured by the president that no tramway owned by a local authority had ever been a success. This remark came in respond to the toast of "The Tramways Institute," in which Mr. W. J. Carruthers Wain referred to the great assistance tramways had been in overcoming the overcrowded state of many towns. He estimated that 600 million people annually enjoyed the use of the tramways at present in England. To provide for such a large traffic, he held that personal supervision by skilled men was required, and that a committee of non technical men could not hope to rule a tramway wisely and well. He proceeded to refer to the energy shown by the institute in opposing harmful legislation, which work had been taken up by his council since 1889.

Mr. SELLON, in replying to Mr. Fell, said that he had no intention of disturbing the harmony of the evening by dis-

Digitized by Google

cussing the merits of one system of haulage over another. The tramway world had had planted in their midst a baby of great promise. The real author of its being he had never been able to discover, though he did know one or two gentlemen who claimed that honour. Apparently the mother was not quite respectable, for she was never mentioned. Now, when there was so much difference of opinion as to origin there must, he (Mr. Sellon) said, be a considerable difference of opinion as it how it should be nurtured, and the unfortunate infant was shown and trotted out to the admiring gaze of local authorities in such various suits, in taste and out of taste, as perplexing to the public mind as it was fatal to the growth and expansion of its many budding virtues. However, he thought that electricity could now be suitably supplied, and with advantage, as a means of traction for tramways. Like Homocea, it touched the spot, and they had only to give it a fair trial and then many pains and ills would be instantly relieved. Mr. Sellon concluded by thanking Mr. Fell for the kind way in which he had introduced his name into the toast.

DUBLIN TRAMWAYS.

The proposed conversion of a large system of tramways like the Dublin United from horse traction to electric traction, is of such manifest interest to the electrical industry that no apology is necessary to refer again to the question, and to put some points forward which strike us after having more carefully considered the report of the engineer.

In June, 1894, Mr. Hammond read a paper before the Association of Municipal Engineers, after having, as he admits, visited most of the systems in use at home and abroad, including South Staffordshire and Budapest. As regards the latter system, he gives it every praise; he mentions the ease with which it works the extraordinary traffic—sometimes much congested—that it successfully deals with, and he gives it his opinion as follows: "The writer wishes to state his conviction that there are many towns in this country (United Kingdom) where a properly-designed and solidly-constructed conduit system would prove a great success." We venture to suggest that Dublin might very well be one of these towns; at any rate we invite the author of the report to tell us the grounds on which he condemns the conduit and introduces an overhead system with the "objectionable overhead wires" (the words are his own) strongly opposed by the Corporation concerned. Clearly it cannot be on account of any failure in working, because he draws attention to "the excellent results," hampered though the system is by having to adopt a metallic return, which is not required in this country. And we must conclude it is for one or other of the following reasons: (1) expense, (2) drainage, (3) width of slot.

Now, all the advantages claimed by the adoption of electricity *quâ* electricity are equally applicable to either the conduit or overhead. We therefore intend to confine our remarks as to the particular form of application.

Expense.—The cost of an installation must, of course, depend on the local conditions and the paying capacity of the tramway. Just as you could not reasonably be called upon to construct a country tramway as expensively as a tramway in a crowded street, so it would not be reasonable to require an expensive system on a tramway that could only support a more economical one. We repeat, each case must be viewed on the local conditions. We are therefore tempted to ask, Has the Dublin United, with the assistance of Mr. Hammond, made out a case to the Dublin Corporation why they should be permitted to use overhead wires, and, to a certain extent, disfigure one, at least, of the finest streets in this country? We emphatically say, "No!" To prove our point, we think we cannot do better than make a comparison between Pesth and Dublin, the population of both towns being nearly the same. At the present moment the Dublin United pay 5 per cent on their inflated capital, which is equal to about £19,650 per double mile of tramway. The large profits made by somebody in the promotion and construction of the tramways has little to do with the Corporation of Dublin.

Taking Mr. Hammond's lowest figures, that the introduction of electric traction will increase the gross receipts 30 per cent., and the working expenditure at 55 per cent., and applying this to the present earnings of the tramway under consideration, we obtain a gross income of £182,000 a year, at an expenditure of £101,100, leaving a profit of £80,900, which is equal to over 8 per cent. on a capital of £977,000, being the existing capital plus the amount required for an installation on the conduit system of electric traction. We do not contend that larger profits may not be made by a reduction of capital due to the introduction of an overhead system, but this has nothing to do with our argument.

This income is also not extraordinary when it is remembered that the Pesth tramway on a mileage nearly five times less than Dublin makes, in gross receipts, £81,330 and pays 8 per cent. on an historically inflated capital.

Drainage.—Mr. Hammond admits that at Pesth difficulties as regards the drainage of the conduit are not met with so as to interfere with the working of the line, as we all know Pesth lies very low, and the fall to the Danube is exceedingly small. Now, the gradients on the Dublin United are, if anything, better than Pesth, and the natural drainage of the town is into the Liffey, with a much better fall than Pesth. The conditions of drainage, therefore, are as good, or better, than Pesth, and no trouble need be anticipated in this direction.

Width of Slot.—Should the conduit system require a slot of the same width as at Budapest, there might be something in the argument. We cannot believe that even Mr. Hammond, however, will press this point; we give him credit for knowing perfectly well the reason of the wide slot at Pesth, and we must also give him credit for knowing that this reason is not applicable to English conditions, and we suggest to him that he has unintentionally misled the Dublin United directors in this respect. It seems superfluous for us to add that any conduit system put down in this country will conform to all the Board of Trade conditions (of which the width of slot is one), and this without any hindrance to mechanical efficiency.

We cannot conclude without expressing our surprise that the Dublin United directorate should have been so indiscreet, or so ill-advised, as to force the Dublin Corporation to appear in opposition before a parliamentary committee to maintain their undoubted rights. The right to grant overhead wire consents is for the people alone to decide, and any tramway company attempting to override public opinion at the present day will be hoisted by their own petard, and are also playing into the hands of municipalisation and to the detriment of the tramway industry generally.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The general meeting of this institute was held at the Cataract House, Niagara Falls, N.Y., beginning on Tuesday, June 25, and continuing for four days. Among the objects of engineering interest which it was proposed to visit were the new works of the Niagara Falls Power Company, the Niagara Falls Park and River Railway on the Canadian side, the aluminium plant of the Pittsburg Reduction Company, the plant of the Carborundum Company, and the central station of the Niagara Falls and Buffalo Electric Light and Power Company.

The list of papers to be read was as follows:

"The Substitution of Electricity for Steam in Railway Practice" (inaugural address), by the president, Dr. Louis Duncan, of Baltimore.

"Properties of Fuse Metals when Subjected to Short-Circuits," by Walter E. Harrington, of Camden, N.J.

"Location of Grounds in Armatures, Fields, etc.," by Clarence E. Gifford, of Jamestown, N.Y.

"Some Features of Alternating-Current Systems," by Chas. P. Steinmetz, of Schenectady, N.Y.

Digitized by Google

"Theory of General Alternating-Current Transformer," by Chas. P. Steinmetz, of Schenectady, N.Y.

"Compounding Dynamos by Armature Reaction," by Elihu Thomson, of Lynn, Mass.

"Existing Commercial Applications of Electrical Power from Niagara Falls," by W. L. R. Emmet, of Schenectady, N.Y.

"Alternating-Current Curves," by Dr. C. E. Emery, of New York.

"Electric Power in Factories," by Prof. Francis B. Crocker, Messrs. Benedikt and Ormsbee, of New York.

"Some Observations on a Direct-Connected 300-kilowatt Monocyclic Alternator," by Profs. Dugald C. Jackson and S. B. Fortenbaugh, of Madison, Wis.

"On Mechanical Models of the Electric Current," by Prof. Brown Ayres, of New Orleans, La.

"On the Cause of Death in Electric Shock," by Albert M. Bleile, M.D., of Columbus, O.

"Long-Distance Power Transmission at 10,000 volts" (the Pomona plant), by George Herbert Winslow, of Pittsburg.

"Notes on the Reconstruction of a Small Central-Station Plant," by Franklin Leonard Pope, of Gt. Barrington, Mass.

"On Rating the Performance of Electric Power Plants and Transmission of Varying Loads," by Prof. Wm. S. Aldrich, of Morgantown, W. Va.

"Work of the Westinghouse Electric and Manufacturing Company for the Cataract Construction Company of New York," by L. B. Stillwell, of Pittsburg.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 448, Vol. XV.)

Part IV.: Calculations of Magnetising Forces.

Part V.: Calculation of Magnet Winding.—In the preceding sections of this serial, Part I.: Calculation of Armature; Part II.: Calculation of Magnetic Flux; and Part III.: Dimensioning of Field-Magnet Frame, have been treated.

The formulæ and tables thus far given enable the complete design of the armature with its winding and all its details; provide the means of computing the requisite magnetic flux to be set up by the field magnet in order to obtain the required output at the given conditions; and, finally, give the best and most economical dimensions of the field-magnet frame of the machine. To complete the design of a dynamo it therefore only remains to calculate the magnetising force required to produce the necessary magnetic flux, and to find a magnet winding which furnishes the requisite magneto-motive force at the specified increase of the field-magnet temperature.

As time does not permit the full treatment of the remaining portion in the columns of the *Electrical World*, the reprint in book form of this serial being in the hands of the W. J. Johnston Company now, the application of the formulæ and tables already given, together with that of the parts not yet published, are, in the following, shown by means of a practical example.

Part VI.: Practical Examples of Dynamo Calculation.—From the numerous cases considered in Part VI. the following may be selected: To design a 300-kilowatt bipolar horseshoe-type dynamo, Edison type, to give 500 volts and 600 amperes at a speed of 400 revolutions per minute. Armature to be a smooth drum; magnets to be of wrought iron, and to have a shunt winding producing a rise of 20deg. C. in field-coil temperature.

I. *Calculation of Armature:* (1) *Length of Armature Conductor.*—In bipolar horseshoe type dynamos not having a pole bushing or pole bridges the percentage of effective armature circumference varies from 67 to 80 per cent., corresponding to a polar arc of from 60deg. to 72deg. respectively. In the present example, which is about the limit, in output, to which a bipolar design can yet be carried, the upper limit of $\beta = 80$ can safely be taken for the ratio of polar embrace; for it follows from Table XV. that the height of the winding space, and, therefore, the length of the air-gaps, increases in a very much smaller ratio than the diameter of the armature, in consequence of which a greater percentage of polar arc in a large-diameter armature will yet produce a higher ratio of distance between pole corners to length of gap spaces (see Table XLVII.) than a small percentage will in a small-size armature.

For $\beta = 80$, Table II. gives the value of $v = 013$ for the unit armature induction. Consulting Table III. and Table IV., we obtain the conductor velocity and the field density best adapted for the case under consideration:

From Table III.: $S = 50$ft. per second.

From Table IV.: $\mathfrak{B} = 30{,}000$ lines of force per square inch.

The total E.M.F. that has to be generated in the armature in order to give an output E.M.F. of 500 volts, by Table VI. is:

$$E = e + 03 \times e = 1\,03 \times 500 = 515 \text{ volts.}$$

By means of formula (3) we can now at once obtain the length of active conductor for the armature—viz.:

$$L_a = \frac{20{,}000 \times 515}{013 \times 50 \times 30{,}000} = 530\text{ft.}$$

2. *Area of Armature Conductor and Selection of Wire.*—From (4) the cross-section of the armature conductor is found

$$\delta_a{}^2 = 300 \times 600 = 180{,}000 \text{ circular mils.}$$

Taking three cables made up of seven No. 13 B.W.G. wires, having 095in. diameter and 9,025cm. area each, we have a total actual cross-section of $3 \times 7 \times 9{,}025 = 189{,}525$cm. the excess amply allowing for the difference between the current output and the total current generated in the armature.

A cable is preferable in case of a large machine carrying a heavy current, on account of the better ventilation effected by air circulation in the spaces between the single wires as well as between the cables.

In accordance with Chapter 10, a single covering of 007in. is selected for the single wires, and an additional double coating of 016in. is chosen for each cable of seven wires; making the total diameter of the insulated cable (see Fig. 136),

$$\delta'_a = 3 \times (095'' + 007'') + 016'' = 322''.$$

3. *Diameter of Armature Core.*—The diameter of the armature core is obtained from the mean winding diameter, formula (6), by means of Table VII.

From (6): $$d'_a = 230 \times \frac{50}{400} = 28\,75\text{in.}$$

From Table VII.: $d_a = 97 \times 28{\cdot}75 = 28$in.

4. *Length of Armature Core.*—The number of cables per layer, from formula (9) and Table XIV., is:

$$o = \frac{28 \times \pi \times (1 - 08)}{322} = \frac{87{\cdot}965 \times 92}{322} = 252;$$

the number of layers, from formula (11) and Table XV.:

$$u = \frac{8'' - 5/32''}{322} = 2.$$

Length of core, from formula (12), three cables being in parallel ($p = 3$):

$$l_a = \frac{\frac{12 \times 530}{252 \times 2}}{3} = \frac{12 \times 530}{116} = 38\text{in.}$$

5. *Arrangement of Armature Winding.*—Number of commutator bars, from Table XVI and formula (15):

$$n > \frac{500 \times 2}{20} < \frac{500 \times 2}{10}; \text{ or } n_{min} = 50, \text{ and } n_{max} = 100.$$

Actual number of armature coils: $n = \frac{252 \times 2}{3} \div 2 = 84.$

Difference of potential between two adjacent bars:

$$\frac{500 \times 2}{84} = 11{\cdot}9 \text{ volts.}$$

Number of turns per coil, by (17): $m = \frac{252 \times 2}{2 \times 84 \times 3} = 1.$

The armature winding, therefore, consists of 84 coils,

* From the *Electrical World* (New York).

Digitized by Google

each consisting of one turn of three cables made up of seven No. 13 B.W.G. wires.

One armature division, containing the beginning of one coil and the end of the one diametrically opposite, is shown in Fig. 137.

6. *Weight of Armature Winding.*—The total length of armature conductor, from formula (21) is:

$$L_t = 530 \times \left(1 + 1{\cdot}4 \times \frac{28}{38}\right) = 1{,}075\text{ft.}$$

Total length of wire, bare, from (2) and wire-gauge table:

$$l\,b_a = 1{,}075 \times 21 \times {\cdot}02732 = 620\text{lb.}$$

Total weight covered, formula (29) and Table XXI.:

$$l\,b'_a = 1\,031 \times 620 = 640\text{lb.}$$

(To be continued.)

A METHOD OF ELECTRIC TRACTION FOR TRAMWAYS IN TOWNS—THE THWAITE-CAWLEY SYSTEM.*

BY GEORGE CAWLEY.

(Concluded from page 746, Vol. XV.)

This is, no doubt, a somewhat jaundiced view of the working of the conduit system in America, and is not given here as representing a fair statement of up-to-date experience, but it is useful in the way of pointing out a substantial defect in conduit plant erected up to the present time—namely, that the conduit is usually too small either to be properly self-cleansing in respect of the mud and water which will find its way through the slot, or to allow examination or repairs to be easily and effectively carried out within it. This defect has primarily arisen from the view that designers of conduit systems have had of the office of the culvert. They looked upon it simply as a convenient location below ground for erecting naked electric mains from which the current could be conveyed by a suitably-arranged conductor passing through the culvert slot to the motor or motors affixed to the cars. With this view, the culvert has been usually made of puny dimensions, and its accessibility for cleaning and repairs has, as a consequence, been impaired, and its efficiency as an important factor in a system been greatly reduced. Owing, then, to the practical difficulties which seemed to stand in the way of economical working of the conduit system, and to considerations of first cost per mile of track, American tramway companies were led to devote their attention chiefly to the single-trolley overhead system, largely because of its initial cheapness, and, further, because the peculiar expansiveness of American freedom relieved them of any thought-of opposition to the system such as would probably be exercised here by our local authorities.

As constructed in America, the single-trolley overhead system takes a shape which may be briefly described as follows: From the generating station the current is supplied at a pressure of usually 500 volts to the motors on the cars through the medium of a bare copper wire, usually about ½in. in diameter, suspended centrally over each line of rails, at about 19ft. above the ground level. This overhead wire is supported at suitable intervals by ingeniously contrived insulators, affixed to wooden or iron posts, and the current is collected from it by means of a trolley wheel and a thin steel tube, mounted upon a spring frame fastened to the top of the car. From this the current is further conveyed by an insulated wire to the controlling and reversing apparatus and to the motors beneath the cars. After the current has done duty in the motors, it passes therefrom to the iron frame of the car, and thence to the rails, which mainly form the return circuit. The overhead conductor is divided into sections of a quarter or half mile in length, insulated from each other, and the current is supplied thereto from the generating station by separate insulated feeders.

Whether these feeders and the sectional conductors, with their supporting poles, are any detriment to the beauty of the thoroughfares along which they are erected, or any real danger to the pedestrian public, is largely a question of personal taste and opinion, but a people who have allowed an overhead railway to be erected and worked in the main street of their commercial capital are not likely to be over-squeamish about such trifles as would probably upset the equanimity of our local rulers here—who are bound, in virtue of their public positions, to pay very considerable attention to the rights of property, and to the view which our English law takes of the sacredness of vested interests. During what may be termed the experimental stage of the single-trolley overhead system in America, the tramway companies made free with other people's property in a manner which would probably bring ruin on a similar company doing likewise in this country.

At the first, it was thought by American electrical engineers that a return circuit could be mainly established through the earth by well earthing the negative poles of the dynamos, but a heavy coal bill soon indicated that a large percentage of electric energy was being lost in transmission. To remedy this, the rails were connected at intervals to the water and gas pipes along the line of route; but this was found to set up an electrolytic action on the pipes, causing serious pitting and corrosion. The condition of things thus became so alarming, that one gas company official is stated to have described the danger as "akin to sitting on the top of a volcano."

This very serious action on the buried pipes could not be permanently allowed even in America, and it was seen that it would be necessary to provide an independent and efficient metallic return circuit, either by means of the rails or by special return conductors taking the whole return current or acting supplementarily to the rails. It is in this direction that recent improvements have largely been made. Where the rails are used as the sole return circuit, great attention is now given to the efficient "bonding" of the rails joints, by specially designed "rail bonds" formed of copper, and inserted in the vertical web of the rails in the most effective manner that the conditions will allow, or by welding the ends of the rails together into one continuous length.

The difficulties arising out of the return circuit in connection with the single-trolley system provides the chief, or perhaps the only, argument for the existence of the double-trolley overhead system, which has been erected to a relatively small extent in America. While the latter system, if properly carried out, ensures an independent metallic return insulated from the earth, and having a low resistance, it must necessarily be highly complex, especially where the tramway route is much curved, and is, therefore, not well adapted to the serpentine course of many streets in our old towns, even if the overhead system of electric traction were permitted at all.

Having regard, then, to the general requirements of British tramway traffic, and to the opposition which many of our local authorities would undoubtedly give to the overhead system in towns, we may not unreasonably conclude that some form or other of the conduit system is the one most likely to be adopted for electrical traction on British urban tramways, and it will, therefore, be well to proceed at once to generally describe the conduit system which forms the special subject of this paper.

In passing, it may be of some interest to explain that the system of electrical traction to which I am about to refer is applicable to canal as well as to tramway haulage. It contains one special feature, which so far as I know, differentiates it from any other system of electric haulage, and makes it equivalent to horse traction as regards mode of operation. That is to say, it can be applied to an ordinary canal boat or tramcar without making the slightest alteration or addition to the boat or car. In the case of the boat, the haulage force, derived from electric energy, is applied directly to the tow-line, and in the case of the car to the drawbar. As we are simply concerned with the tramcar haulage at present, it will not be necessary to refer further to the application of the system to canal traffic, except I may state here that certain figures have been placed before one of our leading canal companies, showing the relative cost of horse haulage and electric haulage by this system under fairly long-distance traffic conditions, and these figures show the present horse haulage to roundly cost three times that estimated for this electric system, which has also the advantage of leaving the towing path open for horse haulage should that be required.

The special feature of this system, to which reference has been made, which enables the present tramway rolling-stock to be utilised for electric haulage without alteration, is one which may contain considerable advantage. All other electric systems, whether of the overhead, conduit, or storage battery kind, necessitate at least the placing of a motor or motors and controlling apparatus upon the car, the strengthening or replacing of the car underframes, and the laying down of heavier track rails to accommodate the increased weight put upon the wheels. In the case of the storage battery system, especially, the question of relative weight upon the car wheels to unit passenger carried is a serious one as regards the initial cost of the rail track and its upkeep. If, therefore, the weight per car wheel, with electric haulage, can be kept as low per passenger carried as is usual in horse-haulage cars, it will be conceded, I think, that some improvement on existing electrical methods has been attained.

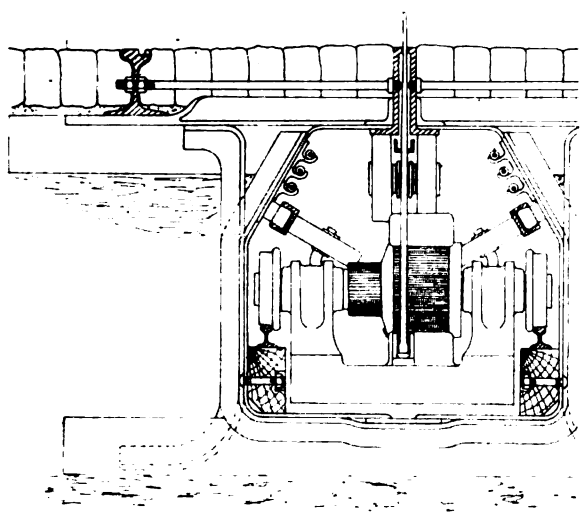
The "dummy" and car are coupled together. The "dummy" is usually carried upon three wheels—a pair of wheels running upon the tram rails, and a centre wheel with a double tread and centre flange running upon the slot girders. It may be carried on four wheels where the nature of the curves offers no difficulty. The "dummy" is driven by a flat bar passing upwards through the slot, and affixed to the hauling locomotive in the culvert, and is attached by a short link or special connecting piece to the ordinary spring drawbar of the

* Paper read before the Tramways Institute of Great Britain and Ireland.

Digitized by Google

tramcar. The "dummy" is provided with a roof and windows to protect the driver during rainy or cold weather, and also carries the switches, rheostat, and other controlling apparatus required for regulating the locomotive running below it, together with the hand-brake lever and spindle for stopping the car. The current is conveyed to and from the "dummy" by insulated flat strips of copper embedded in the driving-bar passing through the slot. The culvert, as shown in the diagram, is 2ft. 9in. wide and 2ft. 6in. high. It is therefore large enough for a man to get freely along it for the purposes of examination and repairs, especially if he reclines upon a small light inspector's trolley running upon the culvert rails, which he could easily push along with his hands by placing them against the side of the culvert. This facility for examination of the culvert and its fittings is so far peculiar to this system, and I venture to think it will be found an important feature.

The culvert may be constructed with the floor and sides of brickwork or concrete, or entirely of cast iron, wrought iron, or steel. As shown on the diagram, it is intended to be constructed of either of the last two named materials. The materials and mode of construction of the culvert will, of course, vary to suit the particular conditions of each case, as, for instance, the nature and weight of the street traffic passing above it. Assuming the culvert to be made of wrought-iron or steel plates and rolled sections, as shown on the diagram, it could be riveted up into convenient lengths of, say, 12ft., with angles at the ends for bolting the lengths together after being laid in position between the line of rails.



At every 300ft. or 500ft. along the culvert—according to the gradient of the line—mud receptacles or wells are placed, having a manhole between the two lines leading into them, and covered by a chequered-iron flap at the street level. Into these wells any mud, dust, or water falling into the culvert through the slot will be swept by the brush attached to the culvert locomotive. The mud deposited in these wells can be lifted out when necessary, or the wells can be connected with the road sewer by a trapped pipe, and occasionally flushed out by a hose. The well manholes serve as entrances to the culvert when examination or repairs are necessary.

The slot in the culvert is $\frac{5}{8}$in. wide, and accommodates a driving-bar 9-16in. thick. The two girders forming the slot are kept equidistant and rigid by tie-bolts connected to the webs of the tram rails, and also by angles riveted to the culvert plates, and embedded into the concrete forming the culvert foundation. The amount of stiffening given to the slot girders is regulated, of course, by the weight of the street traffic above. Longitudinal sleepers of wood rest upon the floor of the culvert and are bolted to its sides. To these sleepers are spiked hard-steel flat-bottomed rails, having a weight of about 27lb. per yard. Along the sloped roof of the culvert are placed notched supports at suitable intervals for carrying insulated feeders. The return circuit can be arranged by an insulated conductor with feeders exactly similar to the conductor carrying the high-potential current from the power station to the motors. These conductors are made of a dovetailed section of channel iron of sufficient area to keep down the resistance within proper limits, having regard to the maximum current required. The conductors are held in position by porcelain insulators bolted to the roof of the culvert, but are free to move longitudinally to allow for expansion or contraction due to the variations of temperature. Each rigid length of conductor is separated by an arranged distance from the adjoining rigid lengths, but electrically connected by bow-shaped strips of copper. The outward and return circuits can be arranged into quarter or half mile sectional lengths insulated from each other, and provided with separate feeders.

The current—say at a pressure of 500 volts—can be conveyed to and from the motors by a pair of trolley wheels—or by a single trolley wheel, where the return circuit is made through the rails—running along the conductors, and kept in contact by means of a spring. Or, as an alternative, the circuit connection between the culvert conductors and the motors can be made by means of a slider or tongue-piece, arranged to slide along the conductor. The trolley wheel method has been successfully applied in America, and should be found even more successful in this case, as the conductor is a rigid bar.

Attached to the upper part of the culvert locomotive is a lever carrying a pair of wheels which run against the lower flange of the slot girders. These wheels press upwards on their rail bed with a force in some arranged degree proportional to the tractive effort required to haul the car. Therefore, when starting the car, or when the car is mounting a gradient, a considerable downward force is thrown upon the locomotive wheels, in addition to that due to gravity, and their tractive capacity is thereby increased. In order that this downward force may be kept within safe limits, the fulcrum of the lever carrying the upper pair of wheels is made to rest upon a kind of spring buffer-head, which yields when a certain prearranged load is put upon the wheels, and in that way any undue strain on the lever or culvert is prevented.

As the upper surface of the rails within the culvert is some distance above the culvert bottom, the haulage locomotive can be partly located below the rail level, and consequently much smaller driving wheels can be used than where the motor armatures are mounted on the car axles, as is usually done when gearless motors are used. The adoption of these small driving wheels permits the motors to run at a higher speed, and to give a greater commercial efficiency than would be conveniently possible with a gearless motor affixed in the ordinary way to the tramcar axles. In the diagram of the wheels which were shown, the scale was slightly under 8in. diameter, or exactly 2ft. in circumference. With this size of driving wheel, when the tramcar travels eight miles an hour, the motor will run at not less than 352 revolutions per minute, and at 12 miles an hour 528 revolutions per minute, which may be considered a fairly satisfactory speed for a directly-connected motor.

The two motors attached to the culvert locomotive have a tractive capacity of 16 h.p., and are capable of giving a sufficiently rapid start to a tramcar carrying 44 passengers on a fairly level line. The method of regulating the motors is similar to that now commonly employed in American practice. The motors are arranged for series-parallel working, so that when getting the car in motion, after a stop, the current may be dynamically utilised as far as the conditions of working will allow. The speed of the tramcar, when either descending a gradient or travelling along any given route, may be limited to a certain prearranged maximum rate by a special governor.

It may be well, before concluding, to briefly allude to the question of constructive and working cost, for this is the crucial question, with regard to which alone the scheme must stand or fall. Dr. Preller's opinion has been already quoted to show that even with the present puny culverts the conduit system will cost at least £10,000 per mile of single line and upwards. From an approximate estimate made for this system on the assumption that the laying of the culvert is not materially interfered with by buried pipes, the cost of construction per mile of single line complete—including paving, the tramway rails, and the concrete rail bed—comes out at about £12,000, of which about half is for the culvert proper. The constructive cost will, of course, vary with local conditions, but where no special road difficulties come in this system could, no doubt, be laid down for the figure named, exclusive of the culvert locomotives, power station, "dummies," and passenger cars.

In connection with the cost of the latter items it should be mentioned that the dummy cars may, if desired, be left out, as the motor-controlling and brake-regulating apparatus can be placed on the end of the passenger car, and the driving-bar, passing up through the culvert slot, connected directly to the drawbar of the car.

As to the working expenses under this system, I venture to think that they would be found relatively very low for several reasons, among which are fewness of repairs and facility for carrying them out, and the reduction of electric "leakage," and consequent waste of energy.

I will now conclude by asking you to accept my thanks for your kind attention, and with a brief recital of some of the advantages which I think may be reasonably claimed for this system.

(1) The culvert is of sufficient dimensions to allow examination or repairs of the conductors or culvert track to be efficiently carried out.

(2) The culvert can be kept quite free from water, mud, or dust by a brush attached to the culvert locomotive.

(3) The locomotive rails being laid inside the culvert the tractive efficiency of the driving wheels is not affected by snow or frost.

(4) When the culvert is once laid, the street traffic need not be afterwards disturbed, except at long-period intervals for the replacement of the tram-line rails.

Digitized by Google

(5) Ordinary horse-hauled tramcars can be used without any structural alterations.

(6) The electromotors used are gearless, and yet run at a relatively high speed and efficiency.

(7) All sparking above the street-level is completely prevented.

(8) All danger to the pedestrian public in the way of accidental electric shocks is entirely obviated.

(9) Posts or other erections along the tramway route are unnecessary, and the appearance of the tramway thoroughfare is not affected.

(10) The tramway rails as used for horse-hauled cars need not be replaced by rails of heavier section.

(11) The system can be conveniently worked in connection with suburban lines using either horse or electric traction.

(12) The load on the driving wheels of the culvert locomotive is proportional to the traction requirements of the car.

(13) The outward and return circuits can be entirely insulated from the earth or buried pipes, thereby preventing any destructive electrolytic action on outside property.

(14) The system in general design is of a character to reduce the cost of repairs to a minimum, and to ensure the durability of the plant over a long period of years.

THE DOVER ELECTRICITY SUPPLY COMPANY'S STATION.

On July 3 the Society of Engineers visited the electricity supply company's station at Dover.

The entrance to the lighting station is by a private road leading from Park-street. The building consists of offices, occupying the west portion, and adjoining these are the engine and boiler rooms. The engine-room, which is faced with glazed bricks throughout, is 100ft. in length by 30ft. in width; the boiler-room is 100ft. long by 45ft. wide.

The engine-room contains the main engines and dynamos, which at present are two 100, one 75, and one 50 kilowatt Mordey alternators, each coupled direct, through a flexible coupling, to Raworth vertical compound-condensing engines, in which forced lubrication is adopted. The alternator bearings are lubricated by means of force pumps. Each main generating unit is controlled by a switch-pillar containing, besides the necessary voltmeters and ammeters, the armature, field, and synchroniser switches, which are interlocking. These switch-pillars throw the alternators on to the omnibus mains which run to the circuit-board through the recording and other instruments. There is at present provision on this circuit-board for six circuits, two of which are for the control of public arc lamps, the remainder being for private lighting. Each circuit is provided with double-pole quick-break switches, fuses, and ammeter. Situated on one side of the engine-room are two continuous-current dynamos, coupled direct to vertical compound tandem engines. These machines feed on to omnibus mains from which the alternator fields are excited. The engine-room also contains two Tangye's centrifugal pumps, coupled direct to vertical engines, which draw water from the River Dour at a point about 100 yards distant, for use in the condensers, attached one to each of the main engines. The pumps draw their supply through two 12in. pipes, forming a duplicate suction, and also discharge into duplicate 12in. mains. A basin has been built in the river bed at a point where the suction pipes draw their supply. All the engines are supplied with steam from a ring main, situated in the boiler-room, and drained by a McDougall steam trap. The floor of the engine-room is about 5ft. above the level of the road. Machinery can thus be readily lifted from wagons by means of a 15-ton crane which traverses the engine-room.

The boiler-room, which is on the road level, now contains two Babcock and Wilcox boilers, each of 200 h.p., working at 150lb. pressure, with space and foundations for five more of the same size. The flue extends along one side of the boiler-room, passes under the front of the buildings, and terminates in a handsome circular chimney shaft 120ft. in height. A Green's economiser of 128 tubes, the scrapers of which are driven by an alternating-current motor, is employed for heating the feed water, which is drawn by two three-throw feed-pipes, either from a well sunk in the boiler-room, or from the tank receiving the condensed water from the main engines, and which can be further heated by the exhaust steam from the auxiliary engines. The feed-pipes are also arranged so that the pumps can deliver water direct into the boilers without its passing through the economiser. The boiler-room also contains a water-meter and a measuring-tank. The engine and boiler rooms are lighted and ventilated from the roof, so as to avoid side windows, and thus reduce any sound to a minimum.

The supply leaves the station at a pressure of 2,000 volts, by Silvertown concentric cables, to some 18 transformer street boxes in various parts of the town, where the current is converted to a pressure of 100 volts and distributed by means of Prescot paper-insulated mains to consumers' premises. There are at present 21 public arc lamps in the streets, each of 2,000 nominal candle-power, and 10 further lamps have been contracted for, to be suspended from arches.

The contract for the whole of the machinery has been, and is being, carried out by the Brush Electrical Engineering Company, Limited. The engineer and manager is Mr. A. J. Lawson. The resident engineer is Mr. A. A. Whitlock.

PHYSICAL SOCIETY.

At the ordinary meeting on June 28, 1895, Dr. Gladstone, vice-president, in the chair,

Mr. Bowden read a note on "**An Electromagnetic Effect.**" A long glass tube, containing mercury and fitted with a small stand-pipe to indicate the hydrostatic pressure, is passed between the poles of an electromagnet. On passing a current of about 30 amperes through the mercury in this tube, the stand-pipe being turned so as to indicate the pressure either perpendicular or parallel to the lines of force of the field of the electromagnet, movements of the mercury in the stand-pipe take place. When the stand-pipe is perpendicular to the lines of force of the field, the mercury rises or falls according to the direction of the current. When the stand-pipe, however, is parallel to the lines of force, the mercury always rises, whatever the direction of the current.

Prof. S. P. Thompson said there appeared to be three unexplained effects—one proportional to the current and the field and reversible, another independent of the direction of the current or of the field, and a third, which only occurred while the current was changing in strength. In addition, there might be a fourth effect, which up to then had not been noticed. The motion of the mercury column was in the opposite direction to that of the drag on the conductor carrying the current. An apparent rise in pressure might be due to a decrease in the density of the mercury, due to the heat developed by the current.

Mr. Blakesley asked if the author had noticed any changes in level in the mercury reservoirs at the ends of the tube.

The **Author**, in his reply, said the reservoirs at the ends were so large that no changes of levels were appreciable

Mr. Rhodes read a paper on "**The Armature Reaction in a Single-Phase Alternating-Current Machine.**" In this paper the author gives the investigations that were the subject of a verbal addendum to a paper read before the society on a previous occasion. He investigates the lag or lead of the E.M.F.'s over the current, and applies the results to examine whether the field excitation of the generator or the motor is strengthened or weakened by the reaction of the armature currents.

Mr. Tunzelmann expressed a hope that the author would amplify parts of his paper.

Mr. Blakesley said the conclusion of the author that "either of two alternate-current machines may be driven as a motor by the other irrespective of their relative E.M.F.'s," is not invariably correct. The facts of the case were these: the E.M.F. of the motor may exceed that of the other machine to a certain extent, but that E.M.F. multiplied by the cosine of the angle of electric lag must yield a product not greater than the E.M.F. of the generator—*i e*, using Mr. Rhodes's symbols, $e \cos \theta$ must not be greater than E. Mr. Blakesley gave a geometrical proof of this, but the same proposition had been given by him some ten years ago in the course of investigating the subject generally. That was at a time when Dr. John Hopkinson was, with less than his usual perspicuity, teaching that synchronous alternate-current machines could not be run in series with stability, both doing work. Referring to the author's diagrams, Mr. Blakesley said that in a problem involving so many elements as that under consideration, it was impossible with the limited dimensions of space to represent the results with the complete generality of a formula. Some elements had to be taken as the independent, others as the dependent variables. The author had considered the power transmitted to the motor, the E.M.F. of the generator, and the angle of electric lag as independent. The E.M.F. of the motor was dependent. In Mr. Blakesley's original diagrams the E.M.F.'s were both considered independent, as well as the electric lag, and the powers applied or transmitted as dependent variables. In any case the formulæ properly derived from such diagrams became perfectly general, and it did not appear to him that the change of method indicated could properly be called a new theory on the subject. As a matter of fact, diagrams based on the independence of the E.M.F.'s and the electric lag would furnish a better means of discussing the question of the stability of the motion than Mr. Rhodes's plan, and this might account for the entire omission from the paper of this important matter.

Prof. S. P. Thompson said it was impossible to discuss the question of stability till the subject of armature reaction had been thoroughly investigated. The terms "lag" and "lead" had been used by Mr. Rhodes in a consistent manner, but this was not always done, and he recommended that the phase of the current which was common to both generator and motor be taken as the standard.

The **Author**, in his reply, said he agreed with Mr. Blakesley that there was a limit to the extent to which the motor might be excited, and this upper limit could easily be obtained from the figure given in the paper. The question of armature reaction was, however, most important, as it might excite the field two or three times more than the original excitation. Since motors were

Digitized by Google

designed to do a certain amount of work, and not the work to fit the motor, it was most natural to take the output of the motor as fixed.

Mr. Shelford Bidwell read a paper on "**The Electrical Properties of Selenium.**" The author has continued his investigations on this subject, and has come to the following conclusions: (1) The conductivity of crystalline Se appears to depend principally on the impurities which it contains in the form of metallic selenides; it may be that the selenides conduct electrolytically, and that the influence of light in increasing the conductivity is to be attributed to its property of facilitating the combination of Se with metals in contact with it (2) A Se cell having platinum electrodes, and made with Se to which about 3 per cent. of cuprous selenide has been added, is even, though unannealed, greatly superior both in conductivity and sensitiveness to a similar cell made with ordinary Se and annealed for several hours. (3) Red Se in contact with copper or brass is quickly darkened by the action of light, owing, it is suggested, to the formation of a selenide. (4) Crystalline Se is porous, and absorbs moisture from the air, and it is this moisture that causes the polarisation of Se after the passage of a current. (5) The presence of moisture is not essential to sensitiveness, but appears to be in a slight degree favourable to it. (6) If cuprous selenide is made the cathode in an electrolytic cell and a strip of platinum the anode in water, red Se mixed with detached particles of the selenide is deposited in the water. (7) The photo-electric currents sometimes set up when light falls upon Se are dependent upon the presence of moisture, and are no doubt of voltaic origin. (8) Perfectly dry Se is below platinum in the thermo-electric series.

Prof Minchin (communicated) suggested that the selenium "cell" should be called a selenium "resistance." A grid having one terminal made of aluminium and the other of copper might form a true cell, and might generate an E.M.F. when light fell on it. He (Prof. Minchin) would like to know if the author had tried any such cell in which light simply and solely generated an E.M.F. He could not agree that chemical action must necessarily follow the action of light in a cell For take the case of the oldest photo-electric cell—the thermopile—what chemical action can we show here for all the energy of the incident heat? Chemical action due to light may or may not occur, according to the nature of the cell.

Mr. Appleyard asked whether the author had submitted these selenium resistances to the action of electric oscillations. Prof. Minchin's impulsion cells were greatly influenced by electric oscillations. The great variation in the resistance with time of the author's cells pointed rather to an effect of contact between the selenium and the electrodes than to an elementary change in the structure or composition. He (Mr. Appleyard) had recently tried to crystallise a supersaturated solution of sodium sulphate by electric oscillation as well as by direct sparks and by currents of several amperes, but no crystals could be induced to form Change of contact, rather than change of structure appeared to him to be the most promising direction in which to look for an adequate theory of selenium resistance.

Prof. Ramsay said the quantity of Se liberated in the electrolytic experiment was much too great to be accounted for by oxygen dissolved in the water. The study of Se was very interesting, for that substance was on the borderland between those bodies in which the electric conduction was metallic and those in which it was known to be electrolytic.

The **Author**, in his reply, said he agreed that the name "selenium cell" was not an appropriate one. He had not tried the effect of electric oscillations.

The society then adjourned till the autumn.

COMPANIES' MEETINGS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED

The half-yearly general meeting of this Company was held at the Cannon-street Hotel yesterday, Mr. S. W. Silver occupying the chair.

The **Chairman**, in moving the payment of an interim dividend of 2½ per cent, or 5s a share, free of income tax, reminded the shareholders that when they last met the prospects could not be said to be very encouraging, and allusion was then made to the caution necessary in opening new accounts in order to avoid losses. Coupled with this was the keen competition that prevailed on all sides, which rendered it necessary that extra care should be taken and great efforts made so that business might not be diminished. Speaking generally, he might say that the works, which were in first-rate order, both at Silvertown and at Persan-Beaumont, had been fairly well employed, with the exception of the submarine telegraph department, in which there were no contracts to report. As a matter of prudence and precaution, it was not, in the judgment of the directors, judicious to pay a higher interim dividend than 2½ per cent. on the present occasion. Subsequently, in reply to questions, he said that they did not propose to alter the usual form of the dividend circular, although the dividend was reduced. They had no further information to communicate with regard to the Pacific cable beyond what was contained in the telegram which we publish in another column, and the reserve fund remained as before.

The motion was ultimately unanimously adopted.

ELECTRIC AND GENERAL INVESTMENT COMPANY, LIMITED.

The ordinary meeting of this Company was held on the 2nd inst. at Winchester House, E C.

Mr. George Herring presided, and, in moving the adoption of the report, explained the principal items of the balance-sheet. He stated that the investments were entered at cost, but were absolutely worth the amount at which they appeared of £69,821. Their general charges increased with their profits. An interim dividend at the rate of 10 per cent. per annum for the half-year was paid last December, and out of the net amount of £5 330 now available for division they proposed to pay a dividend at the rate of 30 per cent. per annum for the past half-year on the ordinary shares, and a dividend of £20 per share for the year on the founders' shares. Taking it that their investments at cost price were of the value stated, then ordinary shares were at the present moment worth £1. 15s. each, plus the goodwill of the business, the capital of £1 a share being intact, the ordinary shareholders' reserve fund representing another 10s, and £5,000 being the ordinary shareholders' proportion of the item of £8,000 set aside as "provision for contingencies." They believed that if the reserve fund were cut up it would produce £140 for each of the founders' shares; the founders' capital of £5 a share was intact, and their portion of the provision for contingencies represented another £30 a share. Including the £35. 16s., also which was now to be paid, the founders' shares were at the present time worth £210, plus the goodwill of the business.

Mr. J. B. Braithwaite jun., seconded the motion, which was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bristol.—The Committee of Visitors of the Bristol Lunatic Asylum, Fishponds, invite tenders by July 15 for supply and fixing the necessary wires, lamps, etc., for lighting the asylum by electricity.

Dortmund.—The Stadtgemeinde invites tenders by August 14 for the construction of a large electric central station. Conditions and plans may be obtained for one mark from Das Magistratsamt, Dortmund, Germany.

Hapton.—Tenders are required for the electric lighting of the village of Hapton from September 1 to April 30, 1896. Number of lights required will be about 50 Tenders to be sent to the chairman of the Hapton Parish Council before July 15.

Wellington.—The Shropshire Iron Company, Limited, Wellington, Salop, invite tenders for the erection of a complete electric lighting plant—two forges, three rolling-mills, one drawing and one galvanising mill, six warehouses, several shops. Plan of ground, etc., may be obtained from the company.

Blackburn.—The Corporation of Blackburn invite tenders for the wiring of the town hall. Copies of the specification may be obtained from the engineer, Mr. E. M Lacey, of 19, Old Queen-street, S.W., on payment of £1. 1s., which will be refunded on return of same accompanied by a *bonâ fide* tender. Plans may be seen at the office of the town clerk, or the engineer, from whom any further information can be obtained. Tenders must be sent in by July 13.

Wellington.—The Wellington (Salop) Urban District Council require tenders for lighting the urban area or lighting district with gas or electricity. The said district comprises about six miles of streets and roads, and is at present lighted by about 200 ordinary gas lamps and three of Sugg's patent treble lights. Further particulars may be obtained from the surveyor, Mr. G. J. Monson, C.E., 45, Walker-street, Wellington. Tenders, endorsed "Tender for Lighting," must be sent to the clerk, Urban Council, Wellington, Salop, by 12 noon on July 15.

Manchester.—The directors of the Manchester Ship Canal Company invite tenders for the work required for the permanent electric lighting of the Manchester and Salford Docks, including alternators and dynamos, arc and incandescent lamps, and cable wires, etc. The drawings may be inspected and copy of the specification obtained on payment of a deposit of £1, which will be refunded on receipt of a *bonâ fide* tender, at the engineer's office, 41, Spring-gardens, Manchester. Tenders, endorsed "Tender for Contract No. 51," must be delivered to Mr. A H. Whitmore, secretary, 41, Spring-gardens, Manchester, by 10 a.m. on July 10.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a *bonâ fide* tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Dewsbury.—Tenders are invited for the wiring of their premises, for the Committee of the Dewsbury Pioneers' Industrial Co-operative Society, Limited. Copies of the specification may be obtained from the borough electrical engineer, Mr. J. B. Mitchell, Electricity Offices, Bradford-road, on payment of 10s. 6d., which will be

Digitized by Google

refunded on return of same, accompanied by a *bonâ fide* tender. Plans may be seen at the office of the borough electrical engineer, Bradford-road, from whom any further information can be obtained. Sealed tenders, endorsed "Electric Lighting," must be sent to Mr. J. B. Mitchell, borough electrical engineer, Electricity Offices, Bradford-road, by July 8.

London, W.C.—The Metropolitan Asylums Board invite tenders for the supply and running of mains in the grounds and for the wiring of buildings now in course of erection at the North-Western Fever Hospital, Haverstock Hill. Conditions of contract and specification, prepared by Prof. Ayrton, may be purchased, price 10s., at the offices of the Board, Norfolk House, Norfolk-street, Strand, W.C. Deposited plans can be seen at the hospital any weekday between 11 a.m. and 4 p.m. on production of the specification. Sealed tenders prepared in accordance with the printed instructions, are to be delivered at the offices of the Board by 11 a.m. on July 18.

Rangoon.—The Rangoon Municipal Committee invite tenders for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc, with the plan of the town, can be obtained on application to Messrs. Ogilvie, Gillanders, and Co, Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders, in sealed covers, and endorsed "Tender for Electric Lighting. Rangoon," to be sent to the president of the Rangoon Municipal Committee by November 4.

Portsmouth.—Tenders are invited by the Corporation for the supply and erection of conduits and indiarubber-covered electric mains, and for the supply and erection of compound-covered high-tension electric mains. Copies of the specification may be obtained from the town clerk at the Town Hall, Portsmouth, on and after July 1, on payment of £2. 2s. for each specification, which will be refunded on the return of the same, accompanied by a *bonâ fide* tender. Further information can be obtained from the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, London. Sealed tenders must be sent to Mr. Alexander Hellard, town clerk, at the Town Hall, Portsmouth, endorsed "Indiarubber-Covered Electric Mains and 'Compound'-Covered Electric Mains," as the case may be, not later than 6 p.m. on July 10.

Brighton.—The Brighton Town Council invite tenders for the supply and erection at their electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping; also for the supply and erection at the electricity works, North-road, of steam and feed piping, cast-iron storage tanks, feed-water filters, electrically-driven feed pumps, circulation economiser, coal-elevator, and sundries. Specifications can be obtained on application at the town clerk's office, Town Hall, Brighton, on payment of one guinea, which will be refunded on return of the specification, accompanied by a *bonâ fide* tender. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, endorsed "Tender for Condensers, etc.," or "Tender for Steam Piping, etc.," must be sent to the town clerk's office, Town Hall, Brighton, by 10 a.m. on July 15.

RESULTS OF TENDERS.

York.—Tenders for the supply of electric lighting plant and fittings for the Corporation have been received as follows:

Electric Construction Company, Wolverhampton	£10,865
Siemens Bros. and Co.	10,345
C. A. Parsons and Co.	10,266
Brush Electrical Engineering Company	8,360

Newcastle-on-Tyne.—The following tenders have been received for the electric light installation in the Presbyterian Church of England, Westmoreland-road:

Bland Bros.	£168	10	0
E. Scott and Mountain	118	0	0
Rowland, Barnett, and Co.	110	16	7
F. Reid, Ferrens, and Co.	95	0	0
Wynn and Barnard	82	10	0
R. J. Charlton and Co. (accepted)	80	0	0
S. Bury	63	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,552.

Electric and General Investment Company, Limited.—The warrants for the dividends, etc., have been posted.

Direct Spanish Telegraph Company.—For the month of June the receipts were £1,884, as against £1,617 for the same period of 1894.

West India and Panama Telegraph Company.—The receipts for the two weeks ended June 30 were £557 less than for the corresponding period of 1894.

City of London Electric Lighting Company, Limited.—The warrants for interest due on July 1 on the Company's 5 per cent. debenture stock have been posted.

Charing Cross and Strand Electricity Supply Corporation, Limited.—Payment was made of the half-yearly interest on the 5 per cent. mortgage debentures due on July 1.

House-Lighting.—Messrs. Drake and Gorham, of 66, Victoria-street, London, S.W., have obtained the contract for the electric lighting of Broome Hall, for Mr. A. H. Browne, M.P.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 30th ult. amounted to £1,193, as compared with £894 in the corresponding week of last year, being an increase of £299.

Dewsbury.—On the recommendation of the Building Committee, the Guardians have decided to have certain additional works done which are necessary to satisfactorily complete the electric lighting of the workhouse.

Chelsea Electricity Supply Company, Limited.—The directors have declared an interim dividend on the 6 per cent preference shares of the Company at the rate of 6 per cent. per annum for the half-year ended June 30, 1895, payable on July 18, 1895.

Metropolitan Asylums Board.—The Local Government Board has written to this authority authorising the laying and fixing of the mains and wires for the purpose of lighting the North-Western Hospital by electricity, at a cost of not exceeding £2,000.

Luton.—The town clerk has received a communication from the parliamentary agents of the Corporation anent the electric lighting question, stating that the confirming Bill was read on June 20 a second time in the House of Lords, and next day passed through committee.

Electrical Company, Limited.—At the general meeting of this Company, held on June 25, a resolution was passed by the Board appointing Mr. F. T. Eggers managing director. It was also decided that an important increase of capital should take place at the fall of the year.

Kingstown (Ireland).—The Town Commissioners have adopted a resolution to the effect that the town surveyor be directed to call the attention of the contractor for the electric tramways to the great inconvenience caused by the depositing of clay and other materials on the footpath

Personal.—Mr. Reginald J. Wallis-Jones, A.M.I.C E., M I.E.E., has been appointed engineer and manager of the Electric Welding Company, Limited, of 21, Hindon-street, London, S.W. Mr. Sydney W. Baynes, M.I.E.E, has been appointed electrical engineer to the St. Pancras Vestry.

United River Plate Telephone.—The accounts for the year ended March 31 show a balance, including £6,417 brought forward, of £16,319, from which the directors recommend, after transferring £3,000 to the depreciation and renewal fund, a distribution of 3 per cent., carrying forward £4,619.

City and South London Railway.—The returns for the week ended June 30 were £780, compared with £1,020 for the corresponding period of 1894, being a decrease of £240. The total receipts for the half-year are £23,873, against £23,638 in the corresponding period of 1894, an increase of £235.

Burnley.—Mr. Bird Clerke, an inspector of the Local Government Board, has conducted an enquiry into an application by the Corporation to borrow £70,500 for various schemes approved by the Council This sum included £3,000 for extending the electric lighting plant, £2,500 for new mains, and £1,000 for Town Hall fittings.

Capital and Counties Electricity Supply Company, Limited.—This Company has been registered, with a capital of £5,000 in £5 shares, for the purpose of carrying on business as electrical engineers and electricians, and to supply electricity for the purposes of light, heat, or power. Office: Palace-chambers, Bridge street, Westminster.

Commission of Sewers.—The Court have decided to carry out experiments in electrically lighting the minor streets of the City at a cost (for the experiments) of £386, and the Streets Committee has been requested, at the suggestion of the Incandescent Gas-light Company, to consider the desirability of experimenting also with incandescent gas lamps.

Newmarket Electric Light Company, Limited.—This Company has been registered, with a capital of £30,000 in £10 shares, with the object of carrying on the business of electrical engineers, electricians, engineers, contractors, suppliers of electricity, manufacturers of electrical appliances, chemical engineers, etc. Office: High-street, Newmarket St. Mary, Suffolk.

Mold.—Considerable satisfaction, a correspondent says, has been given by the decision to include Mold in the Buckley and Chester telephonic free area. The matter has been brought about by the influence of the representatives of Messrs. Thomas Parry and Co. The telephone will be a great boon to the locality, and has been actively taken up by traders, who have felt the loss of its advantages for some time past.

Town and Village Electric Light Company, Limited.—This Company has been registered, with a capital of £100,000, in 19,800 ordinary shares of £5 each and 1,000 founders' shares of £1 each, to acquire as a going concern and carry on the business of supplying electric light, heat, and power, as now and hitherto carried on by the Western Counties Electric Light and Power Syndicate, Limited, at Kingswood, Gloucester, and Keynsham, Somerset.

Wednesbury.—In bringing the report of the Highway, Market, and Stables Committee before the Town Council, a member stated that the Board of Trade had assented to the use of steam upon the Wednesbury and West Bromwich tramways for a further period of three months from the 15th inst. He said it was hoped that by the end of that time arrangements would be made to introduce what the committees of the district desired to see—the electric system on this part of the company's lines.

Digitized by Google

Geo. Piggott and Co.—Messrs. Geo. Piggott and Co., of 110, Cannon-street, London, E.C., have been appointed from July 1, 1895, sole agents for London to Messrs. C. E. Collins and Co, of 55A, Dale-end, Birmingham, makers of high-class electric fittings of all descriptions. They were also recently appointed agents to Mr. F. M. Newton, of Taunton, Somerset, maker of the well-known "Taunton" dynamos and motors.

Fulham.—The Vestry has resumed the debate on the following motion, moved by Mr. Sayer, seconded by Mr. Cranfield: "That Messrs. Kincaid, Waller, and Manville be asked to give the necessary and preliminary advice as to the proposed introduction of electric light into Fulham, with or without a dust destructor, at a fee of £50." Mr. Thelwall had a long amendment referring to the Electric Lighting Committee various points upon which to report as to the effect upon the rates, etc. In the end it was decided to expend the £50, and to refer Mr. Thelwall's amendment to the committee.

Stretford.—A letter was read at the last ordinary meeting of the District Council stating that the Manchester Suburban Electric Supply Company intended to apply in the next session of Parliament for an order enabling the company to supply the district of Stretford with electric light, and asking the Council to facilitate the granting of the order. Mr. J. Wainwright said the question of the company being allowed to come into their district was a very important one, and ought to be well considered. He moved that the communication be referred to the Highways Committee. The motion was agreed to.

Nottingham.—Messrs. Calvert and Co., of 24, Exchange-buildings, Manchester, have secured the contract for the lighting of Colwick Hall and grounds, Nottingham. The installation, which will consist of a boiler, condensing engine, and 24 2,000 c.p. arc lamps, is expected to be ready by August 1. Although a comparatively new firm in this country, Messrs. Calvert and Co. may be recognised in connection with the lighting of the Eccles sewage farm, the outside lighting of the Southport Town Hall for the opening ceremony of the central station there, and the lighting of Mr. Otto Monsted's factory at Southall.

Copper.—Unusually large supplies of copper during June have increased the stocks in England and France and afloat to 58,182 tons, as against 54,211 tons at the end of May. The principal addition was not from North America, Spain, Chili, or Australia, but is tabulated by Messrs. Henry R. Merton and Co. under the head of "other countries," whose quota amounted to 6,874 tons, compared with 703 tons in the previous month. While, however, the total supplies reached 17,422—figures that have only been equalled twice in the last three years— the deliveries also showed considerable improvement, and came to 13,451 tons.

Douglas (I.o.M.).—The want of a tramway to Upper Douglas has, a correspondent says, long been felt, and through the generous offer of the electric tramway company, in consideration of an extension of lease, the project ere long seems destined to become an accomplished fact. In consequence of the want of communication visitors have stopped in the lower part of the town, and consequently in the upper part the value of property has considerably depreciated, and rents have gone down. A petition is to be presented to the Tynwald Court, which has been numerously signed, for leave to introduce a Bill embodying the necessary legislative powers.

Guildford.—A letter has been received by the Urban Sanitary Authority from the Board of Trade with respect to the application by the Guildford Electric Light Company for an extension of time in which to comply with the requirements of Section 7 of the Guildford electric lighting provisional order, and stating that an extension of time until December 17 next had been granted. The Assessment Committee of the Woking Urban District Council applied for the Guardians' consent to the appointment of a valuer to value the buildings and mains of the electric lighting company, and the buildings and mains of the water and gas company, in Woking.

Appointment Vacant.—The Bradford Corporation are prepared to receive applications for the appointment of an engineer to take charge of their electricity works. Applicants must have had experience in similar situations, and must be capable of superintending additions to and extensions of works. Salary to commence at £300 per annum. Print of duties may be obtained on application to the town clerk. Canvassing members of the Council will be a disqualification. Applications, endorsed "Electrical Engineer,' stating age and experience, and accompanied by testimonials, to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by the 17th inst.

Southampton.—The special sub-committee has met for the purpose of conferring with Mr. E. Manville, of Westminster, the electrical engineer engaged to report, on behalf of the Corporation, upon the value of the undertaking and works of the Southampton Electric Light and Power Company, Limited. Mr. Manville attended, and conferred with the committee at length upon the subject, and detailed instructions were given to that gentleman for the purpose of enabling him to prepare his report. Mr. Manville, with the deputy-chairman, subsequently made an inspection of the company's works, and promised to forward his written report as early as possible.

India Rubber and Gutta Percha Company.—The reduction in the interim dividend of this Company from 5 to 2½ per cent., which caused such a heavy fall in the shares last week, is not, the *Financial News* believes, due to any falling off in the Company's general business, but to a special reason. Tenders were invited some time ago for the new Pacific cable, and although nothing has yet been finally decided, the tender of the India Rubber Company was the lowest, and has every prospect of being accepted. It is probably in order to retain as much cash in hand as possible, in case they get the contract for laying the cable, that the directors have reduced the usual interim distribution.

Tunbridge Wells—Owing to some delay in the completion of the machinery, the public lighting will probably not be commenced for several weeks, but in the meanwhile a good many business establishments in the town are being wired in readiness for the current. A curious difficulty has arisen in connection with the installation of the light. A licensed victualler in the town had accepted a contract for the wiring of his house, and the work was commenced, but was stopped by the landlord, a well-known local brewer, who owns a number of licensed houses in which he refuses to allow the light to be installed. One of the reasons given is, we believe, that it would increase the inventory.

Aberystwyth.—The report of Mr. Preece, the engineer appointed by the Town Council to test the electric light in the town, has been received. Mr. Preece expressed himself as satisfied with the result of his inspection, and he recommended that the Council should procure an instrument for recording the power of the light. The report has been discussed at length by the Public Lights Committee, and it was decided ultimately, to recommend the Council to accept it. It was also agreed to instruct the surveyor to obtain prices of the instrument mentioned. In regard to Mr. Aslett's application for a lamp to be placed near the railway station, the town clerk was instructed to write asking Mr. Aslett whether it was the intention of the company to introduce the electric light at the station.

Edinburgh.—At a meeting of the Electric Light Sub-Committee of the Town Council, further consideration was given to the scheme authorised by the Town Council for the extension of the high-tension system to the south side of the city, and instructions were given to the officers to expedite the works, so as to ensure that by the beginning of winter the installation might be completed, parties thus having an opportunity during the summer months of wiring their houses. The same committee considered the subject of the salary of their resident engineer, in view of the large amount of duties undertaken by Mr. Monkhouse, and which were not included in his appointment, especially the road work in connection with the installation. The sub-committee, having regard to the large salaries paid to similar officers in other cities, resolved unanimously to recommend an increase of £100 to the present salary of £300.

Electric Welding.—On Thursday, June 27, the Electric Welding Company, Limited, of 21, Hindon-street, Pimlico, S.W., who own the patents for Great Britain of the Thomson process, exhibited at the conversazione held at the University College, Gower-street, W.C, an automatic wire-welding plant, which, when running, created a great amount of interest. This plant is, we are informed, the same type as that used by some of the largest cable and wire manufacturers in this country. The use of wire-welding plants in America is, it is known, very general, and we understand that the company is already making considerable headway with these machines in England. The Electric Welding Company also showed at the gathering mentioned a large variety of samples welded by their system, including cab and carriage tires, T and angle irons, tubes (butt welds), tool-steel shafts to mild-steel high carbon steel wires, copper wires, etc.

Belfast.—The Electric Lighting Committee of the Corporation have reported that they have accepted the tender of Messrs. S. Z. de Ferranti and Co. for the supply of meters, and that of Messrs. Poole and White for the supply of grip-boxes. They purpose advertising for tenders for the supply of appliances and stores, and for the construction of main extensions which may be required during the ensuing 12 months. They have received an additional grant of £5,000 from the Gas Committee. Alderman Pirrie, in moving the adoption of the report, said it would be gratifying to the Council to know that the extensions referred to in the report were necessary. They had at present 6,500 lamps at work, and the only thing they were not quite satisfied with was the fact that the manufacturers within the district had not made use of the power at their disposal, which would work their machinery cheaper than it was being worked at present. Alderman Lawther seconded the motion, which was passed.

Cheltenham.—The borough surveyor has reported to the Town Council that the electric lighting works are now completed so far as estimated for and in full working order, and the total cost has been £16,880. 14s. 1d., being £880. 14s. 1d. in excess of the original estimate and amount borrowed. The Council has resolved that the engineer estimate for lighting with arc lamps the Promenade to the Gordon Lamp, Clarence-street to the Great Western Railway Station, Ambrose-street, and from thence the High-street to the Royal Hotel, Pittville-street, Winchcombe-street, and Albion-street, to where the main is already laid. The overseers having assessed the electric light works at £400 net, it has been resolved that the town clerk be instructed to appeal to the Assessment Committee against the assessment. A resolution has been adopted in favour of the transference of the duty of dealing with street-lighting from the Streets Committee to the Electric Lighting Committee, henceforward to be called the Lighting Committee.

Lundy.—About 100 workmen are engaged in the erection of two new lighthouses on Lundy Island. As the work will take over two years to complete, two very comfortable barracks have been provided for the men. It often happens that while the present lighthouse is enshrouded in mist less elevated parts of the island are perfectly clear, so neither of the new lights will

Digitized by Google

be more than 200ft. above sea-level, instead of 540ft., as in the case of the old beacon. Such will be the position of the new lights that one or other will be seen from whatever side of the island is approached. For one of the lighthouses the position will be Lametory, on the south-east point of the island, just inside Rat Island, and directly opposite Hartland Point. Here a white light will be fixed, with a fog signal similar to that at the Bishops (Scilly), guncotton detonators being exploded at a distance from the lighthouse by means of electricity. Space for the second lighthouse is being prepared at the north east point, a little west of the Constable Rock The lighthouses, which will be about 3½ miles apart, will be connected by telephone.

Bray (Ireland).—Sir Henry Cochrane said, at the last meeting of the Town Commissioners, that the Bray Improvement Bill had finally passed through Parliament, and it now only awaited the Royal assent to enable them to proceed with the various improvements it authorised. On the morning upon which the Bill came on for hearing they were advised that the Chairman of the House of Lords Committee had intimated to the Chairman of the Special Committee that the authorities of the House had decided that electrical powers be sought by provisional order, and not by parliamentary order, but that the powers to purchase the works and confirm the agreement entered into, and all the other powers sought, would be authorised by the passing of the Bill. Their Council at once accepted the position, which was the only course left open to them. The only other matter remaining was the opposition of the Dublin, Wicklow, and Wexford Railway Company. Now that the Bill had passed, he trusted that no time would be lost in giving effect to its provisions. It was to be regretted that the railway company should have thought it necessary to oppose this Bill in the Lords seeing that it had passed the Commons, and he could not help thinking they were badly advised.

Monmouth.—A local paper publishes an harangue from a correspondent anent the Monmouth electric lighting scheme, of which the following is the concluding portion: "The people have not been consulted. In a public movement of interest to every man, woman, and child in the town, and especially to every ratepayer, who will have to pay yearly his share of the heavy debt that will be incurred in starting and carrying on the electric lighting scheme, it appears to me that before any final step is taken in the matter, the inhabitants should be consulted, and their opinions taken and made known. If slips of paper, written for or against electric light, were delivered at every house, and given to every ratepayer, and everyone were asked to put his mark either for or against, as he wished, those papers would show an immense majority against the electric light. Or if a candidate for a seat at the Town Council went in on the ticket against the electric light, he would enter like a vessel does in a good tide into port. As one who wishes the real improvement, the solid good, and the permanent benefit, as far as they can be secured, without oppressively burdening the poor ratepayers of the town, I venture respectfully to ask the Town Council not to proceed any further with the lighting part of their scheme, before receiving the unmistakable sanction of the majority of the ratepayers to do so."

New London Mains.—The London County Council on Tuesday passed the following notifications of intention to lay mains—from the Westminster Electric Supply Corporation, to lay mains in Davies street, Berkeley-square (north and east sides), Hay-hill, Dover-street, Stafford-street, and Albemarle street, in Davies-street, in and across Robert-street, and in Duke-street, Grosvenor-square (north and west sides), in Victoria-street, thence into Orchard-street, in and across Millbank-street, across Broad-sanctuary into Dean's-yard; from the Metropolitan Electric Supply Company, to lay mains in St. Edmund's terrace, Well's-road, Albert-road, Titchfield-road, Avenue road, Townshend-road, Henry-street, Frederick-street, John-street, Charles street, Townshend-cottages, St. John's Wood-terrace, road, and park, Waranzow-road, Henstridge villas and place, Acacia-road, Ordnance-road, Edward-street, Upper York-place, Eaton-terrace, Queen's road, Outer Circle Regent's Park, Macclesfield bridge, Barrow-hill-road, Chapel-street, New-street, Wilton-place, Park-road, Upper William street, High-street, Marylebone, Cochrane-terrace, Douro-cottages, Wellington-road, Finchley-road, Circus-road, Lennard-place, Elm-tree road, Cavendish-road, Cavendish-road West, Oak-tree-road, Lodge road and place, North-bank, South-bank, Queen's-terrace, Grove End road, Waverley-place, Loudoun-road, Boundary-road, Marlborough-hill, road, and place, Langford-place, Abbey-road, Blenheim road and terrace, Carlton-hill, Clifton-hill, Greville place and road, and Mortimer-road (having regard to the large extent of these works, the Council was of opinion that should any of them not have been commenced within six months of the date of approval a fresh notice should be given in respect of those deferred); from the House-to House Electric Light Supply Company, to lay mains in High-street, Kensington; and from the London Electric Supply Corporation, to lay mains in Bermondsey-street, Market-street, Manning-street, Weston-street, Guy-street, Nelson-street, and Richardson-street.

London.—At the last meeting of the Court of Common Council at the Guildhall, Mr. Lee presented a report from the City Lands Committee asking for authority to appoint Mr. A. A. Voysey as consulting electrical engineer to the Corporation at an honorarium of £50 per annum, subject to annual election by the committee. Mr. Ellis protested against the appointment of another officer, and moved as an amendment that the question should be referred back to the committee for reconsideration. This amendment having been seconded, Mr. Shaw asked if it was possible for the Court to know the relative cost of gas and electricity at the Guildhall. Mr. Lee said the electrical current in 1893 cost £387, and gas £1,312, or a total of £1,700; in 1894 the electric light cost £513, and the gas £882. Mr. Lile reminded the Court that there was a great principle involved in the proposition. For some time past the Corporation had been economising in the amounts spent in charitable directions and the allowances that were made to the committees, and yet it was now proposed to spend £50 a year in appointing a new officer who had up to the present done nothing. Mr. Burnett remarked that the city surveyor had no one in his office who had a knowledge of electrical engineering Mr. Hollington said he had always understood that Mr. W. H. Preece was the consulting electrician to the Corporation. If that was so, why, he asked, was an attempt being made to create another office? He objected to the Court employing an officer who was in the service of a neighbouring body—namely, the Commission of Sewers—for such a purpose, and suggested that if the Corporation needed the services of a consulting engineer it should seek the advice of a professional man and pay the fee or fees, which he did not anticipate would cost £50 a year. Mr. Judd having condemned the proposition, Mr. Lee said it was quite true that the Corporation had from time to time consulted Mr. Preece, but very often that gentleman could not be got at, and the committee thought it would be better if the Corporation had the continuous assistance of Mr. Voysey. The Court, on a show of hands, negatived the report.

Dublin.—The Lord Mayor said, at the last meeting of the Corporation, that it would be well to put the public in possession of the facts in connection with the opposition of the Corporation to the United Tramways Bill last week in the House of Commons. The Bill was introduced last year, and contained no reference to the local authorities of the places where the lines were to run. The Bill contained power for the company to use any form of electric traction that the company pleased—a provision that might cause great public inconvenience. A deputation from the tramways company then waited on the Corporation, said that they were going to adopt the overhead wire system, advised the Corporation to see that system in use in Walsall, Brussels, Hamburg, and other places, and expressed the opinion that when the systems there in use were examined by the Corporation all opposition would be withdrawn. A number of members of the Council went to these cities and reported against the use of the overhead wire system. He also went to those cities, and while confirmed in his belief that the local authority should not have its powers set aside, yet he was impressed with the system in use in Brussels and Hamburg, and came to the conclusion that, subject to proper restrictions, that system might be introduced into some of their streets. When the Bill went into committee in Parliament the Corporation relied merely on their powers as a local authority, and a similar course was adopted by the Pembroke and Rathmines Commissioners. Upon that point it was ruled by the committee that the sanction of these bodies should be obtained to any scheme of electric traction that happened to be proposed. Next day the tramway company announced that, sooner than submit to the local authority in Dublin, Pembroke, and Rathmines, they would abandon their Bill. He thought that that was an unwise thing practically to defy the local authorities. The Corporation had always treated the company with the greatest forbearance. He thought that the attitude now assumed would affect their relations with the company, for that body could not in the future reasonably look for the concessions that they had hitherto got.

Leeds.—The report of the Sub-Highways (Tramways) Committee of the Leeds Corporation, on the subject of tramway haulage, has been considered at a meeting of the Highways Committee. Councillor J. F. Carter, who is also a member of the sub-committee, has all along strongly opposed the adoption of any electrical system, and he again made his protest, though he advocated no alternative system. By another member a question was raised as to whether the recommendations embodied in the sub-committee's report had been passed unanimously. To this, Alderman Firth replied that at the first meeting, when it was agreed to recommend the adoption of electric haulage, every member present voted in favour of this, and that one Conservative member not only voted for electricity, but spoke in favour of it. At the last sub-committee meeting, however, this member (Mr. Denison) had voted against electricity. He (the chairman) challenged Mr. Denison with changing front on the question, and Mr. Denison's answer was that he had only changed his mind once At yesterday's meeting Mr. Mart and Mr. Ringrose expressed themselves strongly in favour of the adoption of the overhead electrical system for the whole city. The former laid particular stress on the fact that the overhead and conduit electrical systems had not hitherto been tried in conjunction He, therefore, thought the Corporation ought to move very cautiously in the matter. He said that if a clause were inserted in the report to the effect that only one short length of conduit would at the outset be tried, he should vote for the adoption of the sub-committee's recommendations. The Chairman informed Mr. Mart that although four lengths of conduit were named in the report, one only would be laid at the outset, and that if the experiment did not prove satisfactory the other lengths would not, of course, be proceeded with. Mr. Mart urged that a statement to that effect should be added to the report. It was not considered necessary to do this, however, and, on the motion of Alderman Ward, a resolution was passed recommending the Council to adopt the report as it stands. It was further decided to request the Mayor (Alderman Gilston) to convene a special meeting of the Council at any early date to consider the matter. In the meantime, copies of the report will be forwarded to every member of the Corporation. The three members of the committee who voted against

Digitized by Google

Alderman's Ward's proposition were Councillor J. F. Carter, Councillor Denison, and Councillor Ringrose. The latter is not opposed to electrical haulage, but objects to the conduit system being recommended for the centre of the city.

Eccles.—At a meeting of the Town Council, held on July 1, Mr. Alderman Kendall, in moving the adoption of the minutes of the Tramways and Electric Lighting Committee, said that the Corporation had obtained a 12 months' extension of the time during which they were to construct the works. The consulting electrical engineer to the borough (Mr. Clirehugh) submitted a report to the committee showing "that for the public and private lighting of the borough combined the capital outlay would be involved of £18,971, but that no charge upon the rates would be necessitated, as while the annual running expenses, including maintenance and machinery, interest on capital and payment to sinking fund, so as to pay off the loan in less than 30 years, would be £2,066, the receipts would be £2,590, or a surplus of £524. It also showed that if the Council were to undertake the lighting of the street lamps only, although the figures for capital outlay and annual cost would come up to not far short of the above figures, there would be a margin of saving as compared with the annual sum at present paid for lighting, etc., of the street lamps, the figures being: capital outlay £15,000 in round figures, and annual cost £1,560, as against an annual sum for gas lighting and other matters which would cease to be expended by the Watch Committee and the Corporation of £1,690, leaving a margin in favour of electric lighting of £130, out of which, however, there would be a sum payable for rates and taxes, which had not been calculated, as it was impossible to say upon what assessment they would be based." Mr. F. Oldfield seconded the motion. Mr. Alderman Mellor admitted that the electrical engineer had done his best to lay before the Council a scheme showing a profit, but his (Mr. Mellor's) opinion was that there would be an increase of a 1d. or 2d. in the pound in the rates. After a lengthy discussion the minutes were confirmed, 10 voting for the resolution and eight for an amendment moved by Mr Alderman Spary that before application was made to the Local Government Board for the necessary borrowing powers, plans, specifications, and tenders should be laid before the Council for consideration. The report of the engineer was afterwards adopted, and the committee were empowered to incur the necessary expenditure required to carry out the provisional order.

Peterborough.—The Town Council in committee have formally adopted the scheme prepared by Mr. Gill, the Corporation engineer, for lighting the central portion of the city with electricity. The scheme is to cost £15,000 Mr. Gill has also submitted a plan for adapting the premises recently acquired in Queen-street for the purpose of an electric light station. The boiler house will be placed on part of the land adjoining, and the plan also provides a chimney shaft, 100ft. high, which will be placed near Messrs. Barford and Perkins's works. The committee has expressed every confidence in Mr. Gill, and decided not to proceed to the appointment of a consulting engineer, as had been suggested. Mr. Gill was asked to push on with the details of the scheme as quickly as possible. Before the work can be commenced the scheme must receive the approval of the Board of Trade, and the Local Government Board will be asked to sanction a loan of money required to be spread over a number of years. The Lighting Committee reported on Tuesday that Mr. Pearson had proposed, and Alderman Hunting seconded, that Mr. J. C. Gill be appointed electrical engineer for the borough, which was carried without dissent, and further, that he paid £100 a year, commencing from June 25. Mr. Beaver said £100 might be a fair remuneration, but taking into consideration the other offices which Mr. Gill held he thought it was too much. In considering the matter of the engineer's salary, which had gone up by leaps and bounds, it had been the understanding that the whole of Mr. Gill's time should be given to the work in which he was engaged. If he was to undertake this fresh department—and he hoped he would—the time which he gave to it must necessarily be taken from that of his other office. He moved, as an amendment, that the salary be fixed in connection with the duties of waterworks engineer, that sum not to exceed £350. At present they were not sure whether the works were going to be successful, and he would rather wait a while and see them fairly started before fixing anything definite. Mr. Cliffe said if Mr. Beaver would alter his motion so as so refer the matter back to committee, he would second it. The Deputy-Mayor asked whether the £100 recommended was in addition to the increase in Mr. Gill's salary as waterworks engineer, recommended some time ago. Mr. Pearson: It was taken into consideration at the time. At the time Mr. Gill asked for this increase it was foreshadowed that he would want more when this work came on. I am rather sorry Mr. Beaver has reopened the matter. Mr. Beaver said he was quite willing that the matter should be referred back to the committee. Mr. Simpson said the question had been debated quite sufficiently in committee already. Mr. J. Hunting, having ascertained that there was no intention of appointing another officer, said the action taken by Mr. Beaver practically amounted to appointing a man to an office, and paying him nothing for the work When Mr. Gill received his last increase he was distinctly asked if he intended it to cover any new appointment, and like an honest man he said "No." It was never intended that it should. They ought to take into consideration the fact that Mr. Gill had practically thrown up a situation of £500 a year because the Council did not wish him to leave, and surely this ought to be some reason why they should give him what he was fairly entitled to. Mr. Miller said there was a difference of opinion in committee on the subject. Mr. Clifton considered Mr. Beaver was acting most unfairly towards Mr. Gill, and he challenged him to find an electric lighting engineer in England who was paid so small a salary as Mr. Gill was willing to accept. It was certainly very poor reward for the great energy Mr. Gill had brought to bear in connection with the preliminary work. Mr. Beaver, in reply, said he had no wish to be unfair to Mr. Gill, and neither did he wish him to do any work for nothing. It was absurd to think he did. Mr. Gill's salary at the present time was £275, and his proposal was that it should be raised to £350. The minute was confirmed by seven votes to three.

Madras Tramways.—There are two aspects of the Madras tramways question—one that presents itself to the plain investor, and the other which its electrical engineer, Mr. Charles H. Gadsby, affords—picturesque, scientific, and making sure of eventual dividends. In the latter, however, the enterprise is admitted to have been a ludicrously slow and uphill affair, and it turns out just as we expected it to be—not the fault of the electric part of the business. Instead of making the decision between steam traction and the resort to electricity, the promoters and authorities are said to have refrained from consulting an expert as to which of the electric systems was best suited to the conditions of Madras. In fact, there must have been a toss, and electricity won it. It may be that the shareholders of the tramways did the right thing in thus stumbling upon the adoption of electric traction without the guidance of electricians, but the inquisition we are upon is, whether intending and future shareholders will be as easily led; and we were looking at the matter more from their standpoint, aware that no class are so timorous as capitalists. It is difficult to treat with Mr. Gadsby's criticisms on our reasons for preferring the Batavian principle of pressure steam haulage for the circumstances of Madras, till satisfied that we are all speaking about exactly the same thing, and that there is no lead off to side issues, such as double *versus* triple expansion, or what they do at home, where it is notorious the instinct is against novelty. Even electric railways had long been in use in America before they were introduced into England. However, it is quite intelligible why the Batavian system has never been advocated for a cold climate, and to state the grounds would be merely recounting those which recommend it for a place like Madras, which is piping hot every day and night in the year. The discussion is really narrowed down by Mr. Gadsby's letter to the very simple point, whether the flatness and extent of field combined with dear fuel—which we in the innocence of the investing public thought were the very last reasons for using electric traction at Madras—are not, on the contray, the strongest in its favour. As to flat roads, they are the best for every tramline wanted to pay, and may be placed out of account. The leakage of electricity carried underground or even near ground level is known to be very great. That of an overhead electric system no one is probably better qualified than Mr. Gadsby to tell us. As to whether even an overhead current of great strength can be insulated without vulcanite or indiarubber by unaided china cups one may be sceptical, but this is of comparative unimportance. What really weighs with investors is the ducks and drakes that one of the cyclones which visit Madras would make of overhead wires. It is difficult to imagine a single wire "over the track." In America there is that one main wire, it is true, but it is supported on cross wires the width of the road, strained between lines of posts on either side. Where lines join at certain corners of streets, there is a very complex arrangement of wires to allow of cars turning and passing each other. The wires over a wide area with tram routes in many different directions would, the higher the observer was stationed, the more closely resemble a cobweb in a rough kind of manner, and the action of the inevitable cyclone is easiest brought home by this figure of speech. Of course, it is not fatal to the success of the tramways—that would be ridiculous—but to shareholders what "interrupts traffic for a few days" may look excusably serious. There is well known to be an enormous wastage of the power of an electric current in transmission along lines of wire, which does not signify where there is water power to generate electricity, but is everything when a steam-engine has to be employed. To state what it is would be of little use, unless we had the figures to give for the loss at Batavia from radiation and condensation, in order to make the comparison. But that loss would be about its minimum at Madras, a much warmer place than Batavia and as warm as any on the earth's surface, it is tolerably certain. The electric loss, on the contrary, would be the same as, or, as the air is moister, probably greater than in England.—*Indian Engineering* of June 8.

Croydon.—We referred briefly last week to the fact that Major-General C. Phipps Carey, R E., an inspector of the Local Government Board, had attended at the Municipal Offices, Croydon, for the purpose of enquiring into an application by the Town Council for sanction to borrow £27,500 for purposes of electric lighting. The Town Clerk said he proposed to call one or two witnesses to show what the Council had done in the matter of electric lighting, to show that there was a demand for electric lighting, and then he would call Prof. Kennedy to explain the details of the scheme. He wished to say, however, with regard to the order of the Board of Trade of 1891—which order could be revoked at any time—that he had written to the Board and had received a letter stating that the Board would be prepared to defer the consideration of the question of revocation of the order for two years, provided steps be taken to give effect to the order without unnecessary delay. Alderman David Buck Miller, J.P., said he was vice-chairman of the General Purposes Committee and chairman of a sub-committee specially appointed by that committee in connection with the proposed introduction of the electric light into the borough. He had for some years past taken a very active interest in the question of introducing the

Digitized by Google

electric light into Croydon. He shortly stated the proceedings of the Council in regard to the question, and said that a provisional order was obtained by the Council authorising the Corporation to carry out the electric lighting and that order was confirmed by an Act which received the Royal assent on July 4, 1891. On November 16, 1891, the Council adopted a recommendation of the General Purposes Committee that they should not then determine what steps should be taken to carry out the provisional order, but should wait and see how electric lighting in the hands of the Corporations of Bradford and Brighton might develop, and also see what decisions might be come to by several of the corporations which had then obtained electric lighting orders, but had not decided upon the mode of carrying them into effect. The Council were at that time and for a long period much divided in opinion as to whether it would be better to transfer the powers conferred by the provisional order to some company, or whether it would be better for the Corporation itself to take the responsibility of carrying out the work. On February 11, 1892, the committee reported an offer they had received from a firm of electrical engineers for the transfer of the electric lighting order, but the Council did not accept that offer. On July 25, 1892, the Council had in consideration a renewal of the offer on slightly different terms, but did not accept it. The committee then advertised inviting offers for the transfer of the powers of the Corporation. Offers were received and were reported by the committee to the Council on September 22, 1892. The Council on September 26, 1892, upon the recommendation of the committee, resolved that they would carry out the powers of the order themselves, either then or at a future date. On January 18, 1893, the committee brought up a recommendation that the Corporation should carry out the lighting of the compulsory area, and that an application should be made to the Local Government Board for sanction to a loan. That recommendation was referred back to the committee, as were also subsequent ones. The matter slept until October last year, when the committee recommended to the Council that an arrangement should be made with some contractors to carry out, on behalf of the Corporation, the powers of the order, but that the contractors should maintain and work the undertaking for a term of years, guaranteeing the Corporation the interest and sinking fund upon the capital expended. The recommendation came before the Council on October 29, 1894, and was adopted *nem. con.* Witness believed that the members of the Council who previously had opposed the introduction of the electric light fully concurred in the recommendations of the committee, which were adopted on October 29. He had made enquiries of the traders in the centre of the town, and found that a great majority of them were prepared to agree to take the light. In several of the new buildings recently erected in the High-street in consequence of the improvements there, private installations had been, or were being, put up; but he had reason to believe that as soon as electricity could be supplied from a central station these private installations would be thrown out of gear, and that the occupiers of property would gladly take the electric light. The Corporation were themselves erecting a new town hall, including courts and free library and reading-room, and would be large consumers there of electric light. Witness had very thoroughly gone into the details of the scheme, for which it was proposed to borrow £27,500, and considered that the scheme adequately provided a system which would serve as a nucleus for the general installation of the electric light throughout the borough. With regard to the site of the electric light installation, the proposal now submitted to the committee contemplated that the station should be erected upon land belonging to the Corporation, and adjoining their dust depôt at Brimstone Barn. This land was close to the railway, and a siding could be conveniently arranged. It was also near to a branch of the Wandle, from which water could be pumped for the purpose of the works, and into which the water could again be returned after use. It would, in his opinion, be preferable, if it could be so arranged, to use a portion of the ground purchased by the Corporation under the Allotments Act, and witness proposed to seek the authority of the Council to lay before the Local Government Board a proposal to appropriate a portion of the allotment ground, purchasing at the expense of the electric lighting undertaking a corresponding area of land close by, and, of course, liberally compensating the tenants of the allotments who might have to shift. The allotment ground would be preferable, because a larger area could be made available, and it was much nearer to the stream, and also would be more conveniently available for a siding from the railway. Communications had from time to time been had with the Board of Trade with regard to the delay that had taken place on the part of the Corporation in carrying out the powers of the provisional order, but witness believed the Board would not revoke the powers of the Corporation if the Local Government Board sanctioned the present scheme. Prof. A. B. W. Kennedy stated that he had had considerable experience in advising upon and carrying out electric lighting works all over the country, both in London and for the Corporations of Glasgow, Edinburgh, Oldham, Belfast, Aberdeen, Sunderland, etc. He had carefully considered the scheme proposed to be carried out in Croydon, and considered it adequate and suitable for the purpose. The system proposed was a high-tension alternating system, which would satisfy immediate requirements, and would permit of extension as required to the outlying districts of the borough without unreasonable expense. Witness put in a map of the borough showing the compulsory area, and also an estimate showing how he arrived at the proposed expenditure of £27,500. The position chosen for the central station, as described by Alderman Miller, appeared to be well chosen and thoroughly suitable. Witness found no other site in Croydon which was by any means so suitable for the purpose. It was close to the railway, from which a coal siding could be made, and was also sufficiently near the Wandle to allow of the steam-engines being worked with condensation. It was proposed to put down, in the first instance, three steel multitubular steam-boilers, each capable of evaporating 6,750lb. of water per hour from cold feed. There would be two feed pumps, each being capable of delivering 1,800 gallons per hour, and a fuel economiser. In the engine-room it was proposed to start three compound vertical condensing engines, each driving an alternating-current dynamo of about 120 kilowatts capacity direct, and either one or two alternators, with battery—for running at times of light load without the necessity of using steam—the necessary exciters for this plant, condenser and air-pump, and suitable switchboards and instruments complete. It was further proposed to erect the station of sufficient size to accommodate machinery to generate electricity for the supply of an extended area. With regard to mains, it was proposed to have in the first instance three or four high-pressure feeders to the centre of the town, each ending in transformer sub-stations, and having in all a carrying capacity of 120 amperes, which, at 2,000 volts would give 240 kilowatts. The network of distributing mains would be at low pressure, either two or three wires, as might be found most convenient. All consumers in the central area would be supplied from low-tension mains direct. Isolated consumers would be supplied from the high-tension mains by the use of separate transformers. The mains would be concentric throughout, and would be carried out so that the permission of the Board of Trade could be obtained to earth the outer conductor in the station. It was proposed to have five transformer sub-stations with suitable transformers and equipments. The apparatus provided for would be sufficient to supply current for 10,000 lamps connected, which witness, having considered the subject, thought a suitable number to start with. He was of opinion that the estimate of £27,500 was a fair and reasonable estimate, and believed that the work contemplated by the Corporation could be adequately carried out for that sum. The Inspector thought that the Local Government Board would require more detailed plans than he had before him. For instance, there were no detailed plans whatever of the building. Prof. Kennedy said he could prepare further plans and send them on to the Local Government Board. The Inspector asked whether the company would accept the plant provided? Prof. Kennedy said they had supplied their own specifications, and had agreed to all the details he had given the inspector. The Inspector asked if the estimate of £27,500 was absolutely necessary to supply the electric light to this area. Prof. Kennedy said it provided for a larger building than would be necessary for the supply of the larger area. The Inspector said he would like to know something about the company to whom the Corporation was going to transfer its power. The town clerk handed in the report of the General Purposes Committee of April 4, 1895, referring to the arrangements between the two bodies, etc. He added that the name of the company was the British Thomson-Houston Company, and in the case of any hitch in the negotiations the Corporation reserved to themselves the right of negotiating with another company. Such a contingency had not arisen, and as yet the agreement had not been sealed, but was waiting the result of the present enquiry. In answer to the inspector, Prof. Kennedy said that nothing would come out of the rates. At Brighton and Bradford they were making a profit, while at Aberdeen and Oldham during the first year of working they both paid the whole expenses of the installation, the whole of the interest, and, in the case of Aberdeen, the whole of the sinking fund. There was no opposition to the scheme.

York.—A special meeting of the City Council has been held to further consider the report of the Streets and Building Committee, acting as the Electric Lighting Committee for the city, presented to the Council on April 29 last, together with a report of inspections by the Electric Lighting Sub-Committee of works in other towns and estimate of cost of complete equipment, on the same basis, of each of the four schemes submitted by firms whose tenders are reserved for consideration. Mr. Alderman Agar moved the reception of the report of the inspections by the Electric Lighting Sub Committee of the various works. This was seconded by Mr. Walker. Mr. Alderman Wragge asked in the event of the Council refusing to adopt any system of electric lighting in the city, what would be the result if any company started a system within the prescribed area? What would be the rights of those outside the area requiring the light? Mr. Brown asked why they were only going to apply for borrowing powers for £15,000, when the Electric Construction Company's work required £16,465? Mr. Pearson asked, if the Corporation did not adopt a system of electric lighting and left it to a private company, whether that private company might be put on terms with regard to a purchase by the Corporation at a later date. Mr. Alderman Agar said that the figure of £15,000 was put down before they had the full estimate for building, which would come to more than was anticipated at the commencement of the scheme. It was thought that £15,000 would be about the mark. The Town Clerk, in reply to Mr. Alderman Wragge, said that the position at present was that the Corporation had obtained at the beginning a monopoly with regard to the supply of electricity for lighting purposes in the city. So long as their powers remained in force no other body and no person could supply electricity to bodies or persons other than themselves. That was to say, it was quite open for any person to lay down electric lighting plant for lighting for their own purposes,

Digitized by Google

but directly they supplied it to any other persons they would be infringing the rights of the Corporation. Then, again, any private company without parliamentary authority breaking up the footpaths for the purpose of electric lighting would be treated as trespassers. If he was asked what would be the effect of the Corporation refusing to adopt any system, if the Board of Trade found that they had no *bonâ fide* intention of doing so, the Board of Trade would listen to applications from various companies for provisional orders and grant them. Since the Council last met he had received a further letter from the Board of Trade, which he submitted to the Electric Lighting Committee, in which they asked what the Council intended to do, and he replied informing them of that meeting. In reply to Mr. Pearson's question it was impossible to foretell what might happen. As a Corporation they might oppose any application for a provisional order. They could, then, in view of that opposition, come to terms with that company, and certain terms of purchase might be inserted in the provisional order. Mr. Alderman Agar, in moving the adoption of the report, said the particulars of the visit which the committee had made showed how arduous their labours had been. As regarded the tender which the committee recommended for acceptance—that of the Electric Construction Company—he left the advocacy of it to the seconder of the adoption of the report. Mr. Mann, in seconding, pointed out that the installation by the Electric Construction Company embodied what was called the "Oxford" system. The difficulties of the Council in making an installation were twofold—first to make it pay, and next, as far as possible, to get over satisfactorily the day load. They were aware that during the period from midnight to four or five o'clock, unless they wished the light to be intermittent, they must have the machinery going day or night, and one great objection to the alternating current was that it must be kept continually running. Mr. Alderman Wragge said the committee had been very much divided on this question. Their deliberations had extended six years, and their constitution had changed seven times. Three experts had given their opinion, the committee had visited 13 stations, and no less than 26 tenders had been received. It was remarkable that the committee recommended the highest tender, and in departing from the usual custom of recommending the lowest tender he thought sufficient reasons should have been advanced. In criticising the vote of the committee when they recommended the adoption of this particular tender, the speaker said the majority of five was made up of one old member of the committee, one partially new member, and three entirely new ones, whereas in the minority of four were included gentlemen who had gone through the whole question from the outset. Dealing with the adoption of the Electric Construction Company's installation at Oxford, he said that in a city with a population of 45,000 the system had cost £62,538, and was worked from one central and five sub-stations. By adopting the system recommended they would require a sub-station in whatever district they desired to supply the light, whereas under the alternating high-tension system there was no necessity to have sub-stations. He expected that in York they would require seven sub-stations. In connection with the Oxford system it cost 3½d. per unit to produce, and reckoning the interest and sinking fund at 7½d. they obtained a total of 11d. Assuming they sold the current at 6d. per unit, there was a loss of 5d., which would fall upon the rates. If the outlay at Oxford had been what he had stated, how could they expect the same company would at a quarter the expense supply the ratepayers of York in a much better way, and make the installation a gain rather than a loss? It was all very well to deal with a compulsory area, but it must be remembered that the locality marked out was the locality that would pay best, and if they allowed a company to step in and supply that area the latter would snap their fingers at the Corporation and lay down a low-tension plant, and then the Corporation would have to supply other parts of the city that would not pay so well. Compared with the Brush Electrical Engineering Company, he believed that if they accepted the tender recommended the cost of transformers would be three times as much, and of feed mains twice as much. The town clerk read the following amendment, which was accepted by Mr. Alderman Wragge: "That the tender of the Brush Electrical Engineering Company be accepted, provided an arrangement can be made with them for the making of the plant by the company for a term of years on the basis of their letter of January 31, 1895, but subject to the modifications of the terms thereof." Mr. Alderman Coning said that he had no objection to second that amendment so far as the adoption of the Brush Company's tender was concerned. Mr. Alderman Wragge had, he thought, made out a very good case indeed. Why he objected to the hasty adoption of terms was because he felt that the company were going to have a good chance in being allowed to supply that light in the very heart of the city where there must be the largest demand. It was just possible that they might make a profit for two years, but what would be their position when they took over the concern, which was the very crux of the matter? The moment they got it into their hands, that moment they would be compelled to supply to the area not before included. It might be on terms, but the ratepayers would have to be fairly treated. The limit of two years was not a wise limit—it should be more elastic. That was, they should be allowed to take over the concern within a certain period on terms now to be definitely and distinctly made. Mr. Atkinson urged that by accepting the conditions of the Brush Company the Corporation would be giving itself into the hands of that company. He argued in favour of the tender of the Electrical Construction Company as being the most practicable, and that it would work out the best and cheapest in the end. Mr. Pearson said he knew full well that if the Council did not supply the electric light itself it would let in a company—a thing which he should very much deprecate indeed—but on the other hand he felt that the Council could not possibly, or he as a member of it could not, consent to join in sanctioning a scheme which at the present moment would in all probability be an expense to the ratepayers. He would like to see a company come and establish a system and work it, and that there should be terms made with them giving the Corporation power to take over the system in five or ten years, or at such a time as the city would bear it or be assured that it would not be a burden upon it. He could not vote either for the adoption of the report or for the amendment. The amendment was then put, when four voted for the amendment, 10 against, and 12 neutral. The amendment was, therefore, lost Mr. Purnell dealt with the advantages of the high-tension over the low-tension system, and contended that the value of each must be measured (so far as they were concerned), firstly, by its comparative power to provide and maintain electricity for all purposes; secondly, by its economy in setting up a complete installation; thirdly, by annual cost of its working; fourthly, by its safety or danger to its users and the public; and, fifthly, by its facility to reach all parts of the city and serve with ease all the ratepayers; and it was in that light he wished the Council to view the tenders before them. High tension was the more modern of the two systems, embodied the latest improvements and ideas, and was practically almost universal in America and on the Continent of Europe. All systems embracing low tension were necessarily limited in their power to supply, and could not embrace an area with a five-wire cable of more than 2,000 yards. High tension, with a two-wire cable, would embrace any area they would ever require from a central station in York. Low tension required a much larger central station to contain its plant and accumulators or secondary batteries, and if they added fresh areas, sub-stations in costly districts. High tension could have its one central station anywhere where they could get cheap land for the purpose, and they only required one station. Having gone through the various tenders, he advocated the acceptance of the tender of Messrs. C A. Parsons and Co., which was a high-tension system, but differing somewhat in the means by which it obtained its results. The system was a well-tried one, having been in use at Newcastle for over six years, and to-day the same turbines and cables were in use, and were as good, true, and serviceable as the day they were first put down. He moved "That the tender of Messrs. Parsons and Co. be accepted, subject to arrangements being made to the satisfaction of this Council for the working of the plant by the company for a term of years" Mr. J. S. Gray agreed that Messrs. Parsons and Co.'s tender involved the lowest capital expenditure, and was at least as low as the others for maintenance. He suggested that some such terms as were indicated in the Brush Company's alternative offer should be asked from Messrs. Parsons. Mr. Alderman Agar thought it was only fair that Siemens's should be included. Each firm ought to have the opportunity of saying on what terms they would supply the Corporation for a specified period of years. After some further discussion the amendment was lost, six voting for it and 13 against, eight being neutral. Mr. Scott said he would like to move that they request Prof. Kennedy to draw up a specification on the lines of the report of the city surveyor. They would never get a satisfactory tender until they had made up their minds as to the system they were going to adopt. It was evident that the more they discussed the matter, either the high-tension alternating or the low-tension continuous current would be too costly in their initial stages. In further remarks he said that Prof Kennedy would require to make a special journey, and he then altered his amendment to read to the effect that the matter be referred back to the committee in order that Prof. Kennedy's opinion might be obtained on the question of high or low tension. Mr. Proctor seconded. Mr. Alderman Wragge said this meant the payment of a fee of 100 guineas to ask Mr. Kennedy to tell them what they had already decided. The amendment was lost by a large majority, only the mover and seconder voting for it. Mr. Scott would like the Corporation to get further information as to the two latest corporate installations, Chester and Burnley, and moved the referring of the matter back with that object. The Lord Mayor said he could not accept that. After some little conversation, Mr. Alderman Coning moved, "That the report be referred back to the committee for reconsideration, and with an instruction to ascertain the terms upon which each of the four firms whose tenders they have reported upon will undertake the supply of the plant necessary for the lighting of the city and the working of the same for a term of years." Mr. Alderman Wragge seconded. The amendment was carried by 17 to 4, three being neutral, and on becoming the substantive resolution was agreed to.

PROVISIONAL PATENTS, 1895.

JUNE 24.

12187. **Improvements in telephonic apparatus.** Henry Capel Lofft Holden, Royal Arsenal, Woolwich.

12229. **Improvements in electric resistances and in the manufacture thereof** Heinrich Julius Ferdinand Voigt and Jacob Adolf Haeffner, 6, Lord-street, Liverpool. (Complete specification.)

12244. **Improvements in electro deposition.** John Cameron Graham, 18, Southampton-buildings, Chancery-lane, London.

Digitized by Google

12232. **Improvements in or appertaining to the manufacture of electric cables and of materials therefor.** James Basnett Atherton and George Hinde Nisbett, 6, Lord-street, Liverpool.

JUNE 25.

12283. **Improvements in devices for attaching electric conductors to their supports.** Alfred Julius Boult, 323, High Holborn, London. (Leopold Karl Kugler, Germany.)

12301. **Improvements in dynamos, motors, and alternators.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

12311. **Improvements in contact or collector bars for the overhead conductors of electrical railways and tramways.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

12329. **Improvements in and relating to telegraphic systems and instruments therefor.** Adolf Merrel and Artur Duffek, 8, Quality-court, Chancery-lane, London. (Complete specification.)

JUNE 26.

12374. **Improved means for indicating and controlling the supply of electricity to portable and other electric lamps and apparatus.** Robert Hacking and George Brand, 78, Fleet-street, London.

12394. **A new or improved apparatus for indicating the time and number of telephonic communications.** Erich Kosanke, Carl Fuhr, and Bruno Krausse, 18, Buckingham-street, Strand, London.

12404. **Improvements in electricity meters.** George Hookham, 18, Southampton-buildings, Chancery-lane, London.

JUNE 27.

12412. **A combined heat radiator and electric lamp shade.** Arthur Lester Taylor, 36, Dale-street, Liverpool.

12414. **Improvements in apparatus for electrically lighting vehicles.** Job Thomas Niblett, 20, Devonshire road, Greenwich, London.

12417. **Improvements in the manufacture of positive plates for secondary electrical batteries.** Carl Hugo Weise, 70, Market-street, Manchester. (Complete specification.)

12420. **Improvements in the manufacture of plates for secondary electrical batteries.** Carl Hugo Weise, 70, Market-street, Manchester. (Complete specification.)

12438. **Ventilators for culverts, tubes, pipes, boxes, and chambers laid or fixed in roads and footpaths in connection with the distribution of electricity.** William Weaver, Kensington Town Hall, London.

12468. **Improvements relating to the current supply of electric railways by an auxiliary accumulator battery.** Adolph Müller, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12469. **Improvements relating to electric railway vehicles.** Adolph Müller 45 Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 28.

12477. **Improvements in and connected with the insulation of storage cells, batteries, etc.** Kenneth James Tarrant and Carrington Riddell Gordon Smythe, 12, Idol-lane, London.

12498. **An improved compound for electrical insulating purposes.** Max Meirowsky, 321, High Holborn, London. (Complete specification.)

12499. **Improvements in holders for electric lamps.** Ernest Albert Browning, 12, St. Andrew-square, Edinburgh.

12521. **Improvements in and connected with the electrolysis of oxides, salts, and other compounds.** Joseph Baxeres Torres, 17, St. Anne's-court, Wardour-street, London

12533. **Improvements in electrical alarm devices for steam and other gauges.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Henry Bradt and Melville Marble, United States.) (Complete specification.)

12546. **Improvements in electricity meters** Chamberlain and Hookham, Limited, and Sydney Holmwood Holden, 18, Southampton buildings, Chancery-lane, London.

JUNE 29.

12596. **Improvements in apparatus for automatically governing electric transformers.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

12613. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk-street, London. (Frederick C. Esmond, United States.)

12614. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk-street, London. (Frederick C. Esmond, United States.)

12615. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk-street, London. (Frederick C. Esmond, United States.)

12616. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk-street, London. (Frederick C. Esmond, United States.)

12617. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk-street, London. (Frederick C. Esmond, United States.)

12622. **Improvements in secondary or accumulator cells.** Adolph Müller, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

3412. **Transmitting signals through cables.** Muirhead and Saunders. (Second edition.)

1894.

11069. **Transmitting signals through telegraph cables.** Muir head. (Second edition.)

11241. **Electric lamp.** Boardman.

11559. **Magneto-electric motors.** Lüdeke and others.

12304. **Electric telephone systems.** Frenay-Olyff.

12476. **Electric switching and regulating apparatus.** Raworth.

13082 **Erecting telephonic, etc., wires.** Shore.

14847. **Electric batteries.** Liardet.

14987. **Electrolysis of alkaline salts.** Wise. (Solvay and Co.)

17379 **Electric elevators or cranes.** Willcox. (Eisenwerk vormals Nagel and Kaemp Actien Gesellschaft.)

NOTES.

Quadruple Telegraphy.—We have received a reprint from the *Elektrotechnische Zeitschrift* of a paper read by Herr Jul. H. West, before the Elektrotechnische Verein in March last, on the subject of quadruple telegraphy in America.

Correction.—In the reply of M. Jean Rey *re* "The Qualities of Mangin and Parabolic Mirrors," published in our issue of July 5, the following correction should be made—viz., page 8, line 25, for "mirror of 30cm." read "mirror of 60cm."

"Mining News."—This is the heading which the new financial daily, the *Financial Post*, gives to an item relative to the dividend of the Capetown Electric Lighting Syndicate. Like most journals in their infantine stage, our contemporary is somewhat erratic.

Personal.—Prof. Henry Spooner, C.E., director of the department of mechanical engineering at the Royal Polytechnic, has been appointed by King Alexander of Servia to be a Knight Commander of the Royal Order of St. Sava, as a recognition of his labours in the cause of science. Prof. Spooner is the author of several works in relation to geometry and mechanics.

The Effects of Gas.—At the North London Police Court the other day, Joseph Triggs, aged 46, compositor, of Walsingham-road, who was found drunk in Stoke Newington-road, excused himself on the ground that in the office where he had been at work all night the electric light had broken down; the gas was put on, which made the air so oppressive. He was discharged.

Corruption ?—Considerable stir has been created in Galatz, in connection with the recent adjudication of the construction of the electric tramways in that city to the firm of Georgi and Co., by the arrest of two persons holding high positions on a charge of corruption. What the precise nature of the charge is we are not yet in a position to say, but it is thought to refer to alleged malversation of deposit-money.

Chesterfield Institution of Engineers. — The annual general meeting of the Chesterfield and Midland Counties Institution of Engineers is to be held to-morrow (Saturday) at the Court House, Warwick. There are now 14 honorary members, 10 life members, 224 members, two associate-members, 73 associates, and 27 students belonging to the institution. The bank balance and invested fund amount to £475.

The Jungfrau Railway Project.—The scheme for the construction of a railway up the Jungfrau seems to have at last assumed tangible shape. It is said that a considerable part of the capital of 9,000,000f. of the new company has already been subscribed, and that an Austrian firm has engaged to take shares and bonds to the value of 5,000,000f. on condition of receiving the contract for the electrical portion of the works.

Electro-Athletics.—Electrical engineers were worthily represented at the amateur athletic championship held at Stamford Bridge Grounds, S.W., on Saturday, the 6th inst., when the third and fourth places in the high jump championship were respectively secured by Mr. R. G. Perry, of Messrs. Crompton and Co., and Mr. W. E. Lane, of the Brush Company, both these gentlemen being awarded the standard medal of the Amateur Athletic Association.

Formation of Ozone by the Action of Electric Oscillations.—Messrs. E. Wiedemann and G. C. Schmidt, in *Ann. Phys. Chem.*, show that if, in the preparation of ozone by the influence of the silent discharge, means are adopted to obtain oscillations of a regular periodic nature, the yield of ozone is increased. They, however, only worked at low pressures where the yield of ozone was small—namely, 0·12 per cent.—under the most favourable conditions.

Electric Tramways in St. Petersburg.—The municipal authorities of St. Petersburg seem to have quite a British objection to tramways being worked by means of overhead conductors. They have just authorised the Prince Tenicheff Company, the *Novosti* says, to construct an electric tramway along the Vosnessensky-Prospect, Erbsen-street, and the Kasanskaya, but only on the condition that the cars are driven by current obtained from accumulators placed in the vehicles.

Hunting Tigers by the Electric Light. — A sportsman reports from Calcutta that he uses the electric light in hunting tigers at night. He sits on a raised platform in the jungle and suspends a 5-c.p. incandescent lamp over the bait, which is placed about 30ft. away. Batteries supply current for the light. A switch on the hunter's rifle enables him to throw on the light when he is ready to shoot. The light tends to temporarily blind the tiger, and a good shot can be had before his eyes become accustomed to it.

Books Received.—We have received from Mr. Henry Sell, 167, Fleet-street, E.C., the June supplement of his registered telegraphic addresses, which supplements and corrects the information supplied to his subscribers up to and including May 31 for London and May 9 for the provinces. By permission of the Postmaster-General, Mr. Sell is now able to state the trade or profession of firms in the alphabetical lists, and he will be pleased to add this information in his next edition without charge if firms will inform him what their business is.

Electricity on the Japanese War Vessels.—The Japanese Legation in Paris has forwarded to the French Government a report relating to the recent naval combats, in which it is stated, with regard to the electric installations on board the Mikado's warships, that the interruptions of current which took place were not caused, as has been said, by the recoil of the guns, but by the bursting of Chinese shells. The working of the ordnance manœuvred by electricity was not interfered with. The electric wires used for igniting charges were, however, broken by the vibration set up by the firing of the heavy guns.

German Activity in Italy.—We stated last week that Italy seemed to be at present offering the best field for the development of German electrical enterprise. It is now announced that the Berlin concern which is popularly known as the "Allgemeine" has, in conjunction with Swiss firms under the leadership of the Schweizerische Credit-anstalt and with several Italian banking houses, founded at Zürich a syndicate, entitled "Bank für Elektrische Unternehmungen (Bank for Electrical Undertakings)," which has for its object the buying out of Genoese electrical companies and practically monopolising the supply of current for both lighting and traction purposes in Genoa.

Electrical Taxation in Italy.—In its issue of June 30, *L'Elettricità* gives some particulars of the legislative Bill which proposes to tax gaslight and electrical energy for illuminating and heating purposes in Italy. It consists of eight articles, and promulgates an impost of 2 centesimi per cubic metre of coal-distilled gas, of 8 centesimi per cubic meter of oil-distilled gas, and of 0 60 centesimo per hecto-watt-hour of electrical energy. The consumption for

Digitized by Google

municipal lighting of public areas and for motive power is exempted from the tax. The impost would have to be paid to the State by the supplier upon the quantity of gas or electrical energy furnished to the consumers, he having the right to recover from the latter the amount disbursed.

East London Trades Exhibition.—An exhibition is being organised, under the honorary presidency of H.R.H. the Prince of Wales, in connection with the People's Palace, and will be opened in March, 1896. The classification includes the usual section of an industrial exhibition, but a special feature of the exhibition is that separate sections have been arranged for the work of individual craftsmen, students, and apprentices, and for collective exhibits from polytechnics and other similar institutions. A liberal schedule of prizes has been arranged in these sections. A special section is also being arranged for women's work. The prizes in this section are not yet announced. The committee are also desirous of forming a loan exhibition of works of art.

Obituary.—Mr. J. B. Stearns died at Camden, Maine, U.S.A., on the 5th inst., aged 65 years. Mr. Stearns will be chiefly remembered in connection with the practical application of the duplex system of signalling in telegraphy. He showed how capacity could be added to the artificial circuit by means of condensers in such a way as to successfully balance the static capacity of the line. This made the duplex system a practical and workable system. He visited this country in the early seventies, and the result was the adoption of his system of balancing by the Post Office Telegraph Department in 1873. By means of this system the Department was enabled to work long circuits as duplex circuits, whereas before it had only been possible to apply duplex working to short lines having small capacity.

A New Asynchronous Alternating-Current Motor is described by Dr. Gustav Benischke in Heft 24 (1895) of the *Elektrotechnische Zeitschrift*. He says that the pretty experiments which E. Thomson made in Paris, and V. v. Lang in Vienna, in connection with the phenomena of reciprocal induction and electrodynamic screen effects, are well known. Stefan, he observes, had previously at one of his lectures at the University of Vienna given an interesting demonstration with rapid electrical alternations in conjunction with the Hertz experiments, and deduced therefrom his principle of the smallest magnetic energy. It is upon this principle that Dr. Benischke has constructed an alternating-current machine which yields power at any number of revolutions and goes by itself at any load without starting apparatus. This, Dr. Benischke claims, has not been attained before, even by the Brown motors.

Are You There?—A lunar enthusiast, Mr. Newton Harrison, winds up a thrilling article on "Telephoning to the Moon" in this fashion: "To build apparatus to carry on an experiment of so interesting a nature would necessitate the use of a gigantic coil mounted vertically with its axis in line with the moon. By the use of currents that continually reverse it is possible to project waves into the planetary regions to an inconceivable distance. These wonderful vibrations will strike the moon, embrace it in every part, and give rise with every timed change to a gentle hum. If lives exist on the lunar surface, if the murmur from the earth be heard, they will listen with sadness; they will feel that utter despair that brooks no consolation and stretches out its arms in vain." Mr. Newton Harrison, it is perhaps superfluous to remark, discloses his nationality by his pen. We have heard about that "despair that stretches out its arms in vain" before.

The Telephone Enquiry.—The Select Committee of the House of Commons appointed to consider and report whether the provision now made for the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this provision either by the granting of licenses to local authorities or otherwise, have agreed to the following report, which has just been published: "Your committee have examined numerous witnesses upon the matter referred to them, and have completed their evidence, but have not, in view of the approaching dissolution of Parliament, had sufficient time to consider their report. They have therefore agreed to report the evidence they have taken to the House, and to recommend that a committee on the same subject be appointed in the next session of Parliament to consider and report upon the evidence already taken, and, if necessary, to take further evidence."

For the Paris Exhibition.—M. Devic's scheme for the construction, in time for the Paris Exhibition of 1900, of a revolving bridge, worked by electricity, over the Seine is discussed in the *Journal de l'Electricité*. There would be one central pier, opposite the Esplanade des Invalides, upon which would be pivoted an enormous platform, 136 metres in diameter, connecting the two banks of the river. In the middle of the platform a tower would be built containing cafés and restaurants. A central pivot would support the whole system, in the manner of hydraulic presses, and powerful screw-cranes would serve to raise the structure in order to put the crown in contact with the drums. The impulse to the bridge would be given on each bank by means of 24 rollers, actuated by dynamos, working by friction against the walls of the span. The rotation of the platform would be sufficiently gentle to enable passengers to step on and off it without any trouble.

Measuring Specific Inductive Power.—A new method of measuring specific inductive power has been described by M. Nodon and Prof. Pellat. They employed two metallic spheres of small capacity, placed some distance apart, and connected with an induction coil, and a third, movable, sphere grounded through a telephone. This third sphere is placed between the other two, its position being determined by the point at which no sound is heard through the telephone. The dielectric to be tested is placed between one of the stationary spheres and the movable one, and the latter is moved towards the dielectric until the telephone again becomes silent. The distance between the first and second positions of the movable sphere will then be proportional to the specific inductive power of the dielectric. In using the apparatus, a material whose inductive capacity is known is first employed; the unknown substance is tested from this or a standard. The two specific inductive capacities will be directly proportional to the distances found in the two tests.

Competitions.—The Société Industrielle du Nord de la France offers various premiums—gold, silver, and bronze medals—for the best treatises on certain set themes; competitions to be forwarded to the society before October 1. Prizes will be awarded for the most meritorious papers on the following subjects: The different systems of lifts and elevators, the author to indicate the best methods of avoiding accidents; the different systems of high-speed French and foreign railway locomotives; the construction and working of tramways; the industrial applications of electricity to the transmission of energy, the production of light, and traction; the applications of telephonic apparatus; electrometallurgy; the applications of electricity to the direct driving of machinery in workshops; comparison between the different modes of lighting; the specifications used in France and abroad for industrial electric installations, the author to prepare draft of a new form; the preparation and textile application of ozone; electric bleaching; and the applications of electricity

Digitized by Google

to the manufacture of the various products of the chemical industry.

The Telephone in Sweden.—The Swedish State telephone authorities are, according to the *Daily News*, about to combine the telephone with the State telegraph system. In Sweden everybody is "on the telephone." In future every subscriber will be allowed to make use of his telephone address as his telegraph address. The letters "Rt" (Rikstelefon) will be transmitted free of charge, and the telegraph office receiving a message will look up the addressee in the telephone register and send it on. This will save two or three words in every telegram. Further than this, telephone subscribers will be allowed to telephone on their messages to the telegraph offices for transmission, and they can, if they so desire, have their telegrams telephoned on to their house immediately they arrive at the station. The State hopes to save by this arrangement, as the number of messengers will be reduced. They also hope to do an increased telegraph traffic.

Concentric Mains.—At the recent hundredth meeting of the Société Internationale des Electriciens, M. Grosselin read a paper in which he asked the question whether it was necessary to insulate the outside conductor with reference to the earth, or if it were preferable to put it directly in the earth, according to the English method. In Europe, the author said, it is customary to give this exterior conductor an insulation equal to the half or the third of that required for the interior conductor. Experiments made in the Champs-Elysées district have shown that this insulation was insufficient, and that a difference of potential of 3,000 volts existed between the conductors and between the interior conductor and the earth, but was nil between the outside conductor and the earth. The insulation of the exterior conductor then, the author continued, seems useless. The question has already been studied by Herr Neustadt, of Vienna, who has observed on a network on which alternating currents were being supplied at 2,000 volts, that the exterior insulation always fractured at the moment of the opening and closing of the switches. The conclusion he arrived at, therefore, was that it was not necessary to insulate the outside conductor.

The "Austria" Accumulator. — A new lead accumulator, for which great things are claimed, has recently been tested and apparently favourably reported upon by the Imperial Physical-Technical Institute, Berlin. It was made by the "Austria" Accumulatoren-Gesellschaft W. Engl and Co., of Vienna, and it consisted of six negative and five positive plates 20cm. long, 16cm. wide, and 6mm. thick. The plates were in a transparent celluloid vessel, closed on all sides, out of which they could not be taken without destroying the latter. The vessel was 25cm. high, 13cm. wide, and 17cm. long, and it weighed, with plates and acid, 14·5kg., or 31·9lb. The capacity of the battery was shown to be 26·7 ampere-hours per kilogramme weight of plate. The Vienna *Zeitschrift für Electrotechnik* contents itself with reproducing in full the German official report, with which it seems impressed, promising to return to the subject later. The Berlin *Elektrotechnischer Anzeiger*, on the other hand, besides publishing the complete report, indulges in a detailed and unfavourable criticism of it, and blames the Imperial Technical Institute for issuing bare statements of actualities without drawing conclusions therefrom.

Arc-Lamp Reflectors. — Some shops, especially jewellery establishments, make a practice of enclosing their arc lamps in globes, a portion of the interior of which is silvered in order to serve as a reflector and concentrate the luminous rays upon a particular spot. A lamp thus placed and fixed outside a shop in Havre began, soon after it was put in position, to cause uneasiness to the management. At the end of every half-hour it went out for a few seconds, and then burned as brilliantly as ever, and it was found that this rapid and regular extinction coincided with the fall to the bottom of the globe of a fragment of carbon pencil about an inch long. Ordinary methods failed to discover the cause of the fault and the abnormal combustion of the carbons. Closer investigation, however, disclosed the mystery. The arc was formed a little below the centre of the globe; the focus of the luminous rays reflected on the silvered part of the sphere was directed somewhat above the middle, on to the positive carbon, which, in consequence of the excessive temperature engendered, commenced to waste away in the manner indicated, and ended by detaching itself in small pieces. When re-illumination automatically followed, the previous conditions were reproduced, and half an hour later the same process of breakage, extinction, and relighting was gone through. Acting upon the lesson thus taught, the management of the establishment replaced the reflecting globes by cylindrical reflectors of parabolic section, and the lamps then worked smoothly.

Standard Resistances for Strong Currents.—The new standard resistances of the Berlin Reichsanstalt for measuring large currents by the voltage at the terminals of a known resistance, are described by Dr. Feussner in the *Electrotechnische Zeitschrift*. The first resistance has a value of 100 microhms, and can be used for currents up to several hundred amperes, and for a short time up to 1,000; the second resistance has a value of 10 microhms and is intended for currents up to 10,000 amperes. Instead of the usual bands of metal, these resistances are made of a casting of manganin in the form of a short hollow cylinder, having about the same width as its diameter, and having a thick wall, about equal to a little less than one-third of its outside diameter; numerous holes are drilled through it, parallel to the axis, so as so increase the resistance to the desired amount, and to serve for the circulation of the oil in the bath in which the cylinders are placed. The connectors are made of large copper bars inserted in two holes, parallel to the axis and diametrically opposite to each other, the current therefore flowing through the two halves of the manganin ring in multiple; these terminals are carefully soldered with silver. The connections for the voltmeter are made of manganin strips screwed to the cylinder near where the copper leads enter it, and are soldered with tin. Great care is taken to have the leads sufficiently large; those in the small apparatus are made of round copper bars 15mm. (about $\frac{5}{8}$in.) in diameter, and in the large one about 50mm. (about 2in.) in diameter, being a little less where they pass through the casting. It is not stated why the leads are not formed of manganin in the form of large blocks cast as a part of the original casting, to which the copper is then fastened; this would avoid all thermo-electric effects in that portion of the resistance which is used in the measurement.

Electric Dental Engine.—A dental engine has been patented by Mr. William E. Wheeler, of New York City. The armature runs vertically between the field magnets, its shaft being cone-shaped and fitted in a cone bearing at the lower end, while on its upper end a plane-face wheel, slightly dished in the centre, is detachably secured. At one side is a socket-like bracket, insulated from the motor body by rubber washers, and in the socket turns the vertical stem of a standard with which is connected a horizontal arm normally pressed downward by a spring. The outer end of the arm is bifurcated, and in the members are

Digitized by Google

journaled the drill-operating spindle, on which is a friction wheel with a rubber rim contacting with the plane-face drive wheel on the upper end of the armature shaft. One of the members of the bifurcated arm has a downwardly bent extension adapted to engage a notched segmental support, and by lifting the arm and shifting the friction wheel toward the periphery of the drive wheel the speed is increased, while by shifting the friction wheel toward the axis of the drive wheel the speed is proportionately diminished. By moving the friction wheel to the opposite side of the drive wheel the direction of rotation is reversed, and when the friction wheel is held centrally over the dished portion of the drive wheel the rotation of the spindle ceases. A threaded extension on one of the bearing arms receives the internally-threaded sleeve, to which is secured the cable, in which is the flexible shaft of the drill, and on one side of the motor is an automatic switch and cable rest. It consists of a pair of spring clasp-like arms, with which are connected the + and – terminals of the circuit wire. The arms are separated when the cable is supported in the rest, the circuit then being broken and the motor stopped; but when the cable is lifted out of the rest, as would be the case when work is being done, the terminals contact, close the circuit, and set the motor in operation.

Moissan on Willson's Calcium Carbide.—M. Moissan, whose experiments with the electric furnace are well known, writes to the *Revue Générale des Sciences* to dispute the claim of Mr. Willson to priority for the commercial preparation of carbide of calcium by the same agency. M. Moissan states that his first research in an electric reverberating furnace with movable electrodes was published in the *Comptes Rendus* of December 12, 1892. In the first note he demonstrated the reduction by carbon, under the action of the electric arc, of oxides previously regarded as incapable of reduction. He referred principally to the reduction of the oxides of uranium, manganese, and chromium; but he also mentioned the accidental formation of calcium carbide by the action of vapours of calcium—the furnace being made of quicklime—upon the carbon electrodes. Mr. Willson's American patent is dated February 21, 1893, and is for the electric reduction of refractory metallic compounds. M. Moissan refrains from discussing the form of the Willson furnace, which reminds him of the Cowles and Grabau furnaces. He asserts that Mr. Willson has not in his furnace separated the calorific action of the arc from its electrolytic action. M. Moissan further declares that, whereas at first Mr. Willson regarded the formation of calcium carbide in his furnace as due to electrolytic action, in his later application for a German patent he affirms that it is a simple process of fusion. But M. Moissan's gravest impeachment of the Willson carbide of calcium process is, however, with reference to the question whether the products of reduction are obtained in the electric furnace in the fluid form or in that of powder. In the first Willson patent specification, it is insisted upon that sufficient carbon shall be employed to prevent the formation of a molten bath. Under this condition M. Moissan declares that it is impossible to obtain titanium, which Mr. Willson claims to have prepared. Finally, M. Moissan remarks that, in a patent treating particularly of alloys of aluminium and magnesium, the claim respecting calcium carbide and other products appears to him to be exaggerated, and to be merely a conventional covering phrase without value from the point of view of priority of discovery.

Technical Education.—The foundation stone of a technical school has been laid at Preston. The new school—the Victoria Jubilee Technical School it is to be named—will be an imposing structure, occupying a prominent position in Corporation-street. The architects selected by competition are Messrs. Cheers, Aspinall, and Smith, of London and Blackburn. It has not been deemed necessary to provide an art school or a chemical laboratory as the existing building (Harris Institute) provides ample accommodation in these respects; it also contains good classrooms, a large room (now used for technical classes in the building trades) capable of being fitted as a physical laboratory, and also an excellent lecture-room seated for about 200 students. The new building will contain a shed for weaving and designing, with space to accommodate 80 hand looms and 20 power looms; a preparation room for warping, winding, etc.; a room for drawing and colouring designs or patterns, and for cloth analysis; a textile museum, library, and reading-room; a shed to hold a complete set of machinery to show the processes of cotton spinning; a lecture-room to accommodate 200 students, mainly for classes in weaving and spinning; rooms for classes in mechanics and engineering, and machine and building construction; two rooms for apparatus and designs; one room each for carpentry and joinery, for appliances and practical work in the plumbing trade, and for instruction in electrical engineering. There are four extra classrooms, each to accommodate 50 students, and the necessary lavatories, cloakrooms, offices, etc., usually provided in a building of this kind. The building is capable of extension without the original arrangements being interfered with, and all the rooms are easily accessible. The rooms and corridors are to intercommunicate, are to be well lighted, well ventilated, and properly heated, and the corridors will be of ample width to allow space for the extension of designs, models, appliances, raw and manufactured materials, and for students' lockers. Provision will be made for the installation of the electric light through the building. The unoccupied land will be well laid out with shrubs, etc., and transformed into very pretty grounds, the whole to be fenced in with low wall and rails. The new building will cost upward of £16,000, and in addition there will be required a sum of money for fitting and furnishing it.

Temperatures of Transformation of Irons and Steels.—M. Charpy, in *Comptes Rendus*, in dealing with this subject, states that the metals were heated in a small furnace, the source of heat being a platinum wire, through which an electric current was passed, and the temperatures were automatically recorded by a Le Chatelier pyrometer. The table below gives the critical temperatures observed during heating and cooling, the critical points being distinguished by the letters a_1, a_2, a_3 used by Osmond. With these very soft steels, the point a_1, which is usually more marked the higher the proportion of carbon, is only feebly indicated, and the point a_3 varies greatly both with the nature of the metal and the rate of heating. The point a_2, on the other hand, is very constant and seems to indicate a distinctly reversible change, since it is produced at the same temperature during both heating and cooling. Arnold has also observed this constancy of the point a_2 in soft steels. Mechanical tests made after tempering indicate that the rectilinear break in the curve of extension disappears when the metal has been heated to 750—880deg. and then tempered. When the same steels are heated, after having been drawn in the cold, the curves as a rule are identical with those given by the annealed metal, and this is true also of the tempered metals, which indicates that the changes produced by tempering or hardening are not permanent in the cold and disappear on annealing at a temperature below the temperature of transformation. By rapid heating, however, curves were obtained in which the point 740deg. did not exist or was replaced by a con-

Digitized by Google

vexity extending from 720deg. to 740deg. The facts observed show that the point a_1 (690—700deg.) corresponds with the transformation of the carbon estimated by Eggertz's method, a transformation which markedly increases the hardness of the steel; the point a_2 (740deg.) corresponds with the transformation of iron which is characterised by the rectilinear break in the curve of extension and which slightly modifies the magnetic and mechanical properties; the point a_3 (860deg.) corresponds with a second transformation of the iron which seems to affect more particularly the magnetic properties.

Steel containing	a_1.		a_2.		a_3.	
	Heating. deg.	Cooling. deg.	Heating. deg.	Cooling. deg.	Heating. deg.	Cooling. deg.

Carbon 0·11 per cent., tungsten 0·60 per cent.	—	630	749	740	923	877

Twaddle.—The following, clipped from a non-technical exchange by an American contemporary, is a characteristic specimen of the literature which the public accepts as scientific on account of the jumble of scientific terms employed: "The time is fast coming when it will be easy to understand the physics of the breath of life, or of the oxygen of respiration, which is also the oxygen of combustion; how the inrush of oxygen by way of the capillary gates of the lungs, and the corpuscles of the blood, to the tissue cells of all parts of the system, carries a ceaseless volume of vital energy; how this animating and life-maintaining energy is nothing less than electricity of absolute dynamic strength and sureness—every breath, according to its size, a definite quantity of vitalising, heating, and sustaining energy; and how the flow and charge of this energy, in all parts of the system, will maintain functions and operate organs which it has, in fact, created. The knowledge from which we speak is not yet recognised because it is new, and belongs to a new system of nature so comprehensive as to require for its demonstration a survey for which the present teachers of science are not prepared, not even the most eminent of them. It requires long and elaborate research to bring into one view the facts of chemistry, of physics, of electricity and magnetism, of zoology, anatomy, physiology and botany, and of medicine and surgery, which fall into the demonstration that life is not, as the system now in vogue has it, 'a mysterious potency, always associated with a peculiar form of matter called protoplasm'; and which, 'so far as we know, has always resided, as it does to-day, in little masses of protoplasm, called cells' (Dr. T. Mitchell Prudden); but is the definite direct effect of a stream of electrical energy blown in the protoplasm by the oxygen of respiration; but in view of the whole history of science from Aristotle and Hippocrates to Darwin and Koch—in view of the long roll of demonstrated facts, and of the theories that have held on in the struggle of systems for existence, we may declare with the utmost confidence that the electrical function of the oxygen of respiration in all living things, animal and plant, and the electrical character of vitality in both animals and plants, is by far the surest and best demonstrated, as it is also by far the greatest and most comprehensive discovery the human mind has ever made—even if we take no note of the demonstration, which the system embraces, that all matter is electrically animated, however motionless it seems; that all atoms receive their character from the electrical charge which they carry; that all active properties and functions are electrically established; and that whatever motion exists anywhere in the material universe, from invisible particle to planet wheeling on its vast orbit in space, is due to electrical agency."

Weights and Measures.—The Select Committee appointed to enquire whether any, and what, changes in the present system of weights and measures should be adopted, have agreed to the following report: "They have, in the first place, received evidence from witnesses representing many different interests—(1) official, (2) commercial, (3) manufacturing, (4) trade, (5) educational, (6) professional. They have also received from numerous corporations, school boards, and other public bodies, resolutions without exception in favour of the adoption of the metrical system. Your committee find that almost all the witnesses express a strong opinion as to the complicated and unsatisfactory condition of our present weights and measures, and of the distinct and serious drawback to our commerce, especially our foreign trade, which this system entails, differing as it does from the system (metrical) now adopted by every European nation except ourselves and Russia, as well as by far the majority of non-European countries with which this kingdom trades. The evidence, however, goes further to show that not only is our foreign trade in every branch seriously handicapped, but that the home trade would be benefited if more simple and uniform standards of weights and measures than those now existing were adopted. Moreover, strong evidence was brought forward as to the serious loss of time incurred by English school-children in having to learn the complicated system of tables of existing weights and measures, and the urgent need of the adoption of a simpler system. It was stated that no less than one year's school time would be saved if the metrical system were taught in place of that now in use. Evidence from competent witnesses proved to the satisfaction of your committee that a compulsory change from an old and complicated system to the metrical had taken place in Germany, Norway and Sweden, Switzerland, Italy, and many other European countries without serious opposition or inconvenience; that this change was carried out in a comparatively short period; and that as soon as the simple character of the new system was understood it was appreciated by all classes of the population, and no attempt to use the old units or to return to the old system was made. In the United States, where a system founded on the English units exists, a commission is at present engaged in an investigation of the same character as that with which your committee is charged, and the Federal Government has this year passed an Act rendering the metrical system compulsory for pharmaceutical purposes. Your committee believes that the adoption of the metrical system by England would greatly tend to render that system universal. Your committee recommend: (*a*) that the metrical system of weights and measures be at once legalised for all purposes; (*b*) that after a lapse of two years the metrical system be rendered compulsory by Act of Parliament; (*c*) that the metrical system of weights and measures be taught in all public elementary schools as a necessary and integral part of arithmetic, and that decimals be introduced at an earlier period of the school curriculum than is the case at present." The Select Committee was constituted as follows: Sir John Barran, Mr. Burt, Mr. Crombie, Mr. Charles Fenwick, Mr. Alban Gibbs, Mr. Godson, Sir Edward Hill, Mr. Justin M'Carthy, Sir Samuel Montagu, Mr. Jasper More, Sir Albert Rollit, Sir Henry Roscoe, Mr. James Stevenson, Mr. Stewart Wallace, Mr. Webster, Mr. Whiteley, and Mr. Wrightson. Subsequently, however, Mr. Woods took the place of Mr Fenwick on the committee.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

(BY OUR SPECIAL CORRESPONDENT.)

Acting on the instructions of the esteemed editor of the *Electrical Engineer*, I took a ticket to Munich on Tuesday last week with the view of representing that journal at the yearly gathering of German electrical engineers. My instructions were generally to find out the why and wherefore of the Verband, and the methods by which its objects are attained. I arrived at Munich on Wednesday evening and proceeded to the Rheinischer Hof, where I occupied a room adjoining that of the secretary of the Verband, Mr. Gisbert Kapp, late of Westminster, from whom I received a genial welcome. We breakfasted together on Thursday, the opening day. I found Mr. Kapp eager to get news of personal friends and professional colleagues in England. The first meeting of the general members of the Verband was held for reception purposes at 8 p.m. in the evening. This left a good deal of spare time to be pleasantly employed in exploring the art treasures of Munich. The evening function was held in the Arzbergerkeller, a large restaurant. There I obtained my membership ticket, with the useful additions of a handsome badge, an "Elektrotechniker Taschenbuch"—a neatly-bound note-book and diary containing information on general subjects relating to the profession, and a full programme—a guide to Munich, and a guide to the Starnberg district, which was visited by the members of the Verband on Sunday.

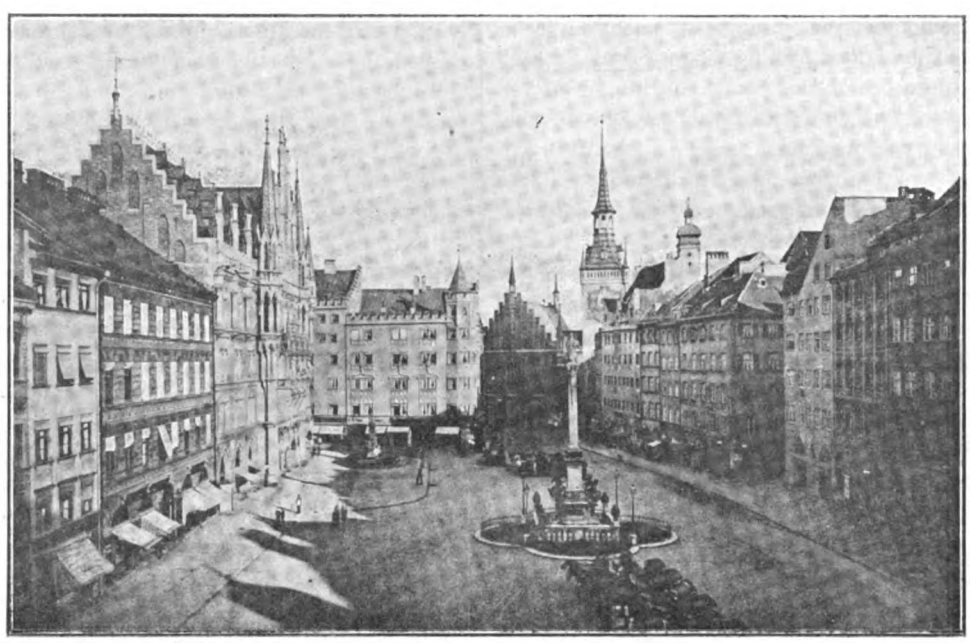
The meeting was held in a large room on the first floor of the Arzbergerkeller, which was decorated in a novel manner. Silver-birch trees newly cut down ornamented the walls, and in the centre of the tables handsome shrubs were placed at intervals. From these, festoons of edibles were hung in tempting proximity to the heads of the guests. Incandescent lamps were also placed in these shrubs, fed by flexible wires from the ceiling. My friend Mr. Kapp was engaged at a council meeting till late, and I had to pick up my acquaintances without introduction. A representative of the Helios Company (Mr. F. Heintz), however, kindly took me in hand. I had many introductions from him to noted German engineers who spoke my native language, amongst whom was Oscar von Millar, the engineer who is responsible for the design of so many German electric lighting stations.

The music provided was good, and the audience sang with great gusto the various topical songs that had been written for the occasion. Other amusements were furnished—such as a dialogue between a comet, a gas lamp, and an incandescent lamp with respect to their own merits as lighting media. The gentlemen with the incandescent lamp in his helmet looked as though he had walked out of the Zürich Incandescent Lamp Company's advertisement.

When I left the Arzbergerkeller, the birch trees and evergreen shrubs were almost all that was left of the decorations.

FRIDAY, JULY 5.

Before proceeding with the account of the meetings held on this day it may be of interest to recapitulate the general objects for which the Verband was established. The society was started in 1893 for the purpose of bringing German electrical engineers into closer contact, and ensuring a permanent representation and advancement of German electrical engineering. This end was to be attained by holding an annual meeting of the members of the society in a German town, which would promote the exchange of opinion on matters of current interest through the medium of papers and discussions, and by the publication of a journal, etc. The official home of the Verband is No. 3, Monbijou-Platz, Berlin. The president is Geh. Reg.-Rat. Prof. Dr. A. Slaby, of Charlottenburg; the vice-presidents are Herr Wilhelm von Siemens, of Charlottenburg, and Kgl. Baurat J. Stübben, of Cologne; the secretary is, as already stated, Herr Gisbert Kapp. Subject to the approval of the committee, any resident in Germany who has a scientific or practical interest in electrical engineering and the allied branches may become a member of the society, the annual subscription to which is 30 marks. There are now 1,600 members. The organ of the Verband, as most readers know, is the *Elektrotechnische Zeitschrift*.



Old and New Rathaus, Munich.

As might be expected in such a large society, friction has occurred, but I do not doubt personally that with careful attention from Mr. Kapp the Verband will be a power for good to the profession in Germany.

The annual report was presented on Friday morning, but the *Elektrotechnische Zeitschrift* has the first right of publication of it and of all the papers read at these meetings. I may, however, allude to the trouble arising over the new fire rules about to be issued by the Verband. The difficulty of devising entirely new wordings makes previous authors jealous. The result here has been that certain engineers object to the new rules, mostly, I gather from several sources, on personal grounds. One disciple of Mr. Musgrave Heaphy's, who introduced his own set of rules by translating those of the Phœnix Company, is a leader in the strife, and imitates his master's standing with regard to the rules about to be issued by the English Institution of Electrical Engineers.

One or two papers were read before the morning meeting closed, and I must commend the German method of

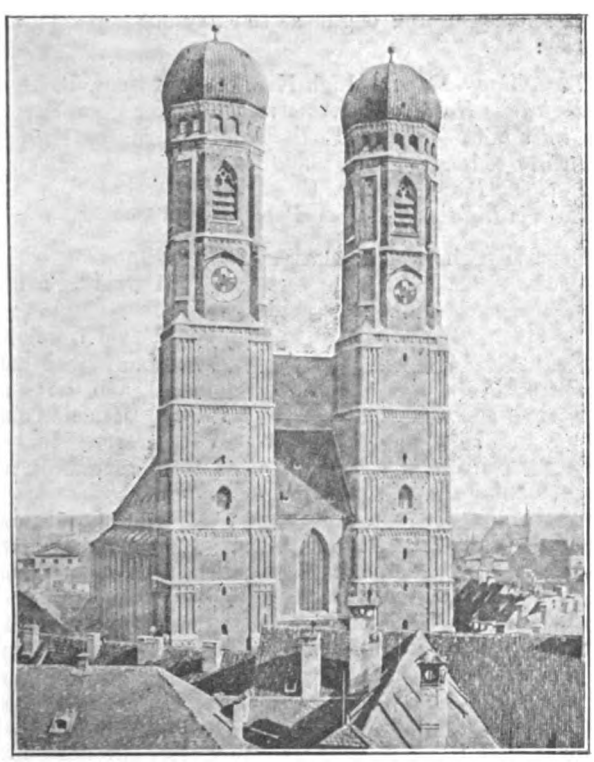
Digitized by Google

extempore speaking. Some of the authors had their papers to refer to; most had not. The result was a concise and brief account of the work contained in the written papers, given with a power that with reading is impossible. This feature and the condensation resulting might be adopted with much advantage by our institution. The

Triumphal Arch, Munich.

paper describing the Munich electricity works was amply illustrated with diagrams, drawings, and models, which were very interesting to all present.

At noon the ceremony of unveiling the statue of Ohm was much hampered by rain. A heavy thunderstorm drenched those of the spectators who were unable to obtain shelter. The statue, which is of white marble,



The Cathedral, Munich.

stands in the square in front of the Technical High School, near the celebrated old picture gallery. The rector of this school unveiled the statue after a suitable ode had been sung. A biographical sketch of Ohm was circulated among the members of the Verband. Georg Simon Ohm was born at Erlangen on March 16, 1789, the son of a master locksmith, who was himself able to initiate his sons in the mysteries of mathematics. Young Ohm's first post was as teacher of mathematics and physics in Gottstadt and Neuenberg, in Switzerland. Thence he returned to his native town, and acted as *privatdocent* at the university there for a short time. From here he wandered to Bamberg, then to Cologne, where, in 1827, he published his chief work, "The Galvanic Circuit Mathematically Elaborated." Later he became a professor at, and ultimately rector of, the Polytechnic School at Nuremberg. He was 60 years of age when he came to Munich, where he worked as a professor in the university and an academician until his death, which occurred on July 6, 1854. Ohm's discovery of the laws of the electric current was admittedly of the very highest importance; and when, in 1881, the electricians assembled in congress at Paris resolved to name after him the unit of electrical resistance, the theory of which he was the first to develop, they raised to him a "monument more lasting than brass," or even than that of marble, which has just been unveiled to him in his beloved "München."

(To be continued.)

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 9.)

We will not ourselves plot this curve any further, but will suppose the curve handed us as in Fig. 3. There

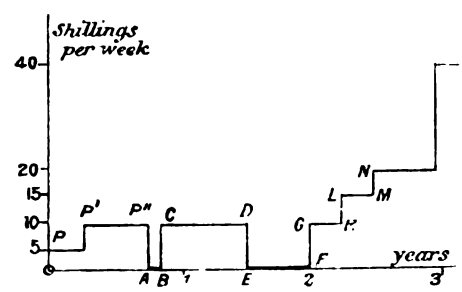


FIG. 3.

is a rumour abroad to the effect that a certain young electrician made use of such a curve when applying for a post, and, when asked what he had done previously, handed in his reply in the shape of a curve.

For obvious reasons of space, we must adopt a different scale in Fig. 3 from that used in Fig. 2. It is customary to append the necessary information as to scale and quantities plotted, in the manner shown in Fig. 3; in fact, Fig. 3 is complete in itself, and requires nothing to make it perfectly intelligible to anyone who understands a curve, or who has even read the first article of this series.

One of the best ways of attacking a curve is to tabulate all the points in the manner exemplified below. We first measure the length marked 10 on O Y, and find it to be 1cm., and the length marked 1 along O X we find to be 1in. All we have to do now is to measure the position of each point by finding its distance from O, first along O X and then along O Y.* Having put down the dimensions, we can at once translate them into the quantities represented.

Point.	Distance from O along O X = time			Distance from O along O Y = income.		
P	0	=	0	0·5cm.	=	5s. per week.
P'	¼in.	=	3 months.	1·0	=	10s. ,,
P''	¾	=	9 months.	1·0	=	10s. ,,
a	,,	=	,,	0	=	nothing.
b	⅔	=	10 months.	0	=	,,
c	,,	=	,,	1·0	=	10s. per week.
d	1½	=	18 months.	1·0	=	10s. ,,
e	,,	=	,,	0	=	nothing.
f	2	=	2 years.	0	=	,,
g	,,	=	,,	1·0	=	10s. per week.
l	2¼	=	2¼ years.	1·5	=	15s. ,,
n	2½	=	2½ years.	2·0	=	£1 ,,

* The horizontal direction will always be referred to as O X and the vertical as O Y.

Digitized by Google

and so on. Of course, the parts of the curve, *a b* and *e f*, show times during which he was earning nothing, but they do not tell us why. We have to guess why; and here let me remark that it is commonly the duty of curves to show us facts of which we have by independent reasoning to arrive at the cause.

Briefly summarised, this curve, Fig. 3, says that this person started at 5s. a week, had his money doubled after three months, and remained at 10s. a week for 1½ years. He was away from work for a month of this time, and at the end of the time again for six months. Starting at the same wage again, he had a couple of 5s. rises in six months, and a £1 rise at the end of the next six months.

We will not proceed to the study of particular shapes of curves until we have looked at one more example. Let us take Fig. 4. In this we see space and time connected by a line. This curve has only one sharp point in it, and, when we think of what is represented, we can readily understand that sharp points would not occur. We are shown changes of space in corresponding changes of time, and, since we are measuring space from a given point it is plain that a motion is represented. Now, the motion of any body which has mass cannot change absolutely suddenly, the change must be more or less gradual. Let it be clear that length on this curve does not mean motion in the sense of velocity. Length up O Y means space, or distance passed through; and length along O X means time, again, as in Fig. 3: velocity can only be represented by considering both at once; but more of this later on; let us first read what appears on the surface of this curve.

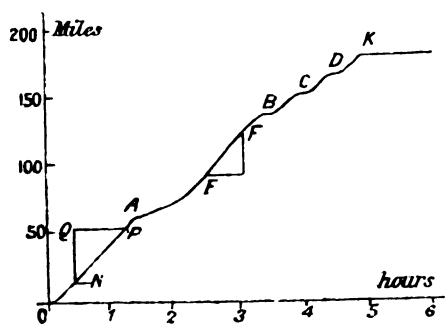

FIG. 4.

During the time, six hours, we see a change in position of 185 miles; on measuring the scale we find it ½in. to the hour and 1in. to 100 miles.

We see little flats in the curve at *a*, *b*, *c*, *d*, and a long one at K. What do they mean? At these points distance along O X increases, but not along O Y. From this we learn that time has increased, but distance has not; in brief, the body is at rest at these points and is not moving at all. Between *n* and *p* the curve is straight, and we find on measuring that *q n* and *q p* are each ½in.—that is to say, the change of length along the direction O Y is ½in., and the change of length along O X is ½in., so that the body has moved 50 miles in that hour, *q p*. If we measure at the points *e* and *f*, we shall find a change of ¼in. along O X, and ⅓in. along O Y, or a change of 33·3 miles in half an hour.

This curve might very well be the history of a certain railway journey, showing stoppages at *a*, *b*, *c*, and *d*; the steepness of the curve showing, as must now be apparent, the speed of the train. It is well, when looking at a curve of this sort, to be very careful indeed to remember that, although distance along O Y means distance in this case, distance along O X means *time*, and therefore this is not a map of the train's track; the train might have been going round a circle the whole time for aught the curve tells us on the point. "Distance travelled" and "time" are the quantities connected. If it were a map, distance north and distance east of the datum point would be what we measure along O Y and O X respectively.

Just a word about the sharp corner just before *k*; this shows a sudden change in the direction or steepness of the curve—that is, in velocity—and points to a collision, especially as it is followed by so long a stoppage.

A very great deal might be said about this curve with regard to the interpretation of its waviness, the meaning of which has been hinted at; but before going thoroughly into the examination of a curve representing physical facts, we must take up the study of a few common curves for their own sakes. This study is known as geometry—co-ordinate and analytical geometry—and may be read up in any of the numerous books on the subject. These articles are not designed to take the place and do the work of such books, but to treat of the subject only so far as is absolutely necessary for the handling of such curves as are to be commonly met with in practice, and that in an elementary, simple manner.

(To be continued.)

GLASGOW HARBOUR TUNNEL.

The Glasgow harbour tunnel, which was opened last week, will provide a means of cross-river communication in the middle of the harbour, where it has long been required; and as it will put the Queen Docks, on the north side of the river, into direct communication with the new Cumock Docks, on the south side, its advantage will be more felt when these latter docks are finished.

So much has the want of some means of communication between the extensive engineering works on the north side of the river and the south side been felt, that various schemes have been suggested of building high-level or swinging bridges with inclines to them; but the necessary stoppage of the river traffic for even a short time was recognised as an insurmountable obstacle to a bridge of any description, as most of the cross-channel steamers start from above this point.

It was left to Messrs. Simpson and Wilson, however, to put forward a scheme for constructing tunnels under the bed of the river, and the approaches to which, instead of being by means of inclines, was by lifts or elevators. The scheme was sanctioned by Parliament in 1890, and work was soon after commenced. The following contractors were selected by the engineers to carry out portion of the works:

Tunnelling—Messrs. Hugh Kennedy and Sons, Partick.
Hydraulic Hoists—The American Elevator Company.
Girder Work—Messrs. Findlay and Co., Motherwell.
Boilers—Messrs. Penman and Co.
Pumping Plant—Messrs. Cross, Haron, and Co.
Electric Lighting—Messrs. Paterson and Cooper.

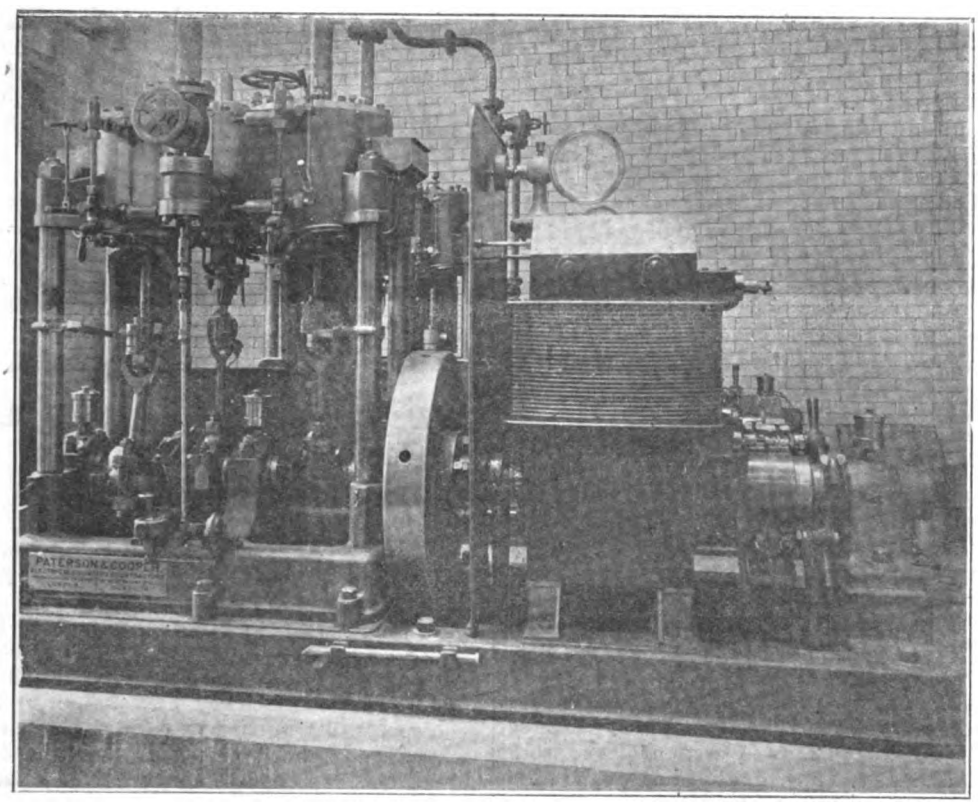
Generally, the works consist of three tunnels—two for vehicular traffic and one for foot traffic. This latter tunnel, which is the centre one, is reached by stairs on either side of the river, while the other two run on a level from shaft to shaft.

These tunnels are 16ft. internal diameter, and the length from shaft to shaft is a little over 700ft. Both shafts are round and 76ft. in diameter and 75ft. deep. In each shaft there are six hydraulic hoists—three for lifting and three for lowering—but any one of them can be used for lifting or lowering when required; the maximum load to be lifted is about 5½ tons. The passenger tunnel pierces the shaft 34ft. from quay level with flights of stairs, as above mentioned, and thence descending by a gradient of 1 in 3, the same level as the other tunnels being reached at the quay walls. This arrangement with stairs in shaft and incline obviates the necessity of lifts for passengers.

We might here remark that the whole of the mechanical portion of the works has been carried out by Mr. D. H. Morton, M.I.M.E., A.M.I.C.E. Electric light necessarily plays an important part in such an undertaking as this; and one of the points that the engineers had in view in placing the contract for the work was that the installation should be of such a nature that the damp and moisture that has to be contended with should do no damage to the leads, etc. The usual methods that have met with more or less success were suggested, such as lead-covered cables, cables in iron pipes, etc., but Messrs. Paterson and Cooper, of London and Glasgow, suggested what might almost be called a modification of the Brooks system of town mains—

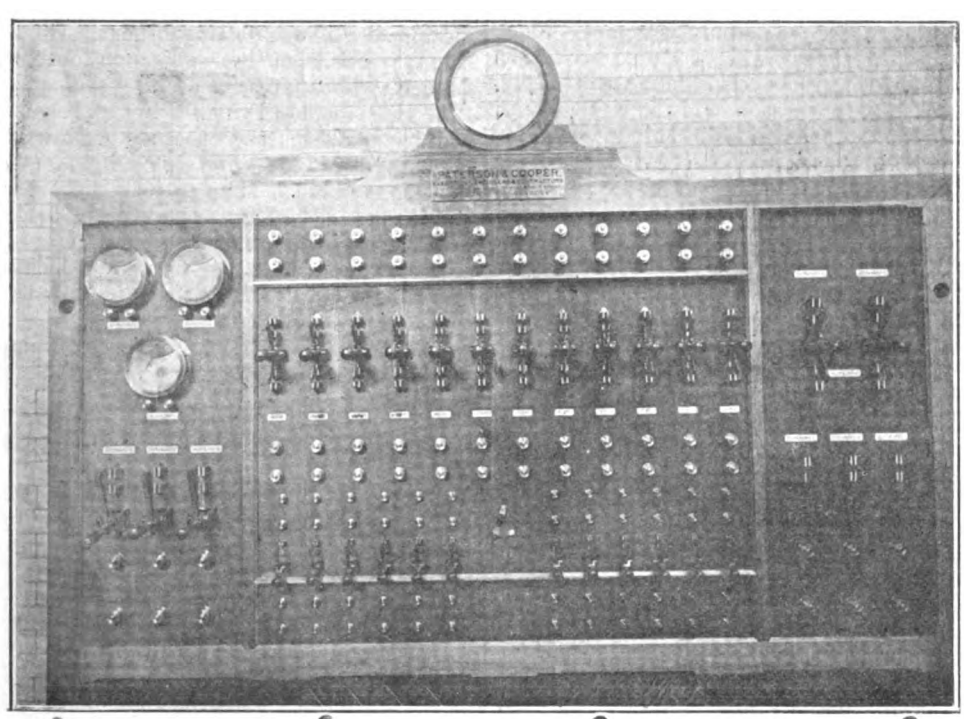
Digitized by Google

that is to say, to use specially-covered cables, run in iron pipe and filled entirely with a preparation of resin oil. It is obvious that by this means all possibility of damp reaching the wires was perfectly overcome; and we must congratulate the engineers upon adopting this system, as, although it is considerably more expensive than any other system, they have an installation that will practically last for ever.



Direct-Driven Dynamo.—Glasgow Harbour Works.

The plant consists of three sets of direct-coupled plant—two sets of 20,460-watt output each, and one small auxiliary set of 6,050-watt output. The plant is placed in the main engine-house, which contains also the pumping and lift plant, and is situated on the south side of the river. The two large sets of plant consist of inverted-type wrought-iron dynamos, coupled on to compound engines by G. H. Belliss and Co., of Birmingham. The dynamos, as will be seen in the accompanying illustration, are of the ordinary type. They give 186 amperes at 110 volts at 300 revolutions per minute, are compound wound, with the series winding on the outside. The armatures are of the improved Gramme ring type as now made by Messrs. Paterson and Cooper, and they run absolutely without sparking at the brushes. The engines are of the Belliss central-valve type, having cylinders 8½in. and 13in. diameter, and 6in. stroke. They indicate 34 h.p. with a steam pressure of 95lb. The governor is fitted direct on to the crankshaft, and controls the throttle. A variation of less than two volts only is experienced between full and no load,



Switchboard.—Glasgow Harbour Works.

Digitized by Google

Special precautions are taken to ensure dry steam, drip pipes being fitted directly above each engine, besides the ones on the main branches. The small dynamo is exactly similar in construction to the other two, but has an output of only 55 amperes at 110 volts at 300 revolutions per minute. The engine is also by Belliss and Co., but is only a single-cylinder engine, but of the same type otherwise as the two compound engines. Tachometers are fitted on each of the sets of plant.

The switchboard—an illustration of which is given—is designed so as to effect the greatest economy in power with the greatest facility in manipulation. It consists of five slate tablets mounted in a pitch-pine frame. On the right-hand tablet are the three main positive dynamo switches and fuses, and also the throw-over switches to throw the auxiliary dynamo on in place of either of the two large sets when the load on the latter falls sufficiently. The left-hand tablet contains the main negative switches and fuses, and an ammeter for each dynamo. The top tablet contains the negative-circuit fuses, and the bottom tablet contains the negative arc lamp fuses. The centre tablet contains all the positive fuses, the arc lamp switch, and circuit throw-over switch.

The installation is divided into 11 circuits as follows, one spare circuit being provided for on the board: (1) north shaft A; (2) south shaft A; (3) north shaft B; (4) south shaft B; (5) foot tunnel A; (6) foot tunnel B; (7) east wheel tunnel A; (8) east wheel tunnel B; (9) west wheel tunnel A; (10) west wheel tunnel B; (11) engine-house, etc.; (12) spare.

The switches are arranged so that any circuit can be thrown on to either dynamo (whether it happens to be one of the main machines or the auxiliary plant that is being used). It will be noticed that every section of the work is in duplicate, so that the chance of a breakdown and total extinction of the light is very remote.

The duty of the various plants will be as follows. During the day, when the lights will be required only at the bottom of the shafts and through the three tunnels, one of the large sets will do the work. Then at night and morning, when there is not much traffic, and all the lifts are not required, the auxiliary plant will take up what the main plant cannot do; but when traffic is heavy, and all the outside lights are also wanted, both large sets will be at work. During the night, when only the foot tunnel will be open (the wheel tunnel will be closed to traffic between midnight and 5 a.m.), the small plant will easily do all the work. Should, however, one of the large plants be put out of use on account of overhauling, etc., the heaviest traffic could always be perfectly well carried on with the other two sets by switching off every alternate light in the tunnels, as it would still leave ample light for all practical purposes.

The lamps are distributed over the works as follows: north shaft, 10 arc lamps; south shaft, 10 arc lamps; foot tunnel, 50 32-c.p. lamps; east wheel tunnel, 25 32 c.p. lamps; west wheel tunnel, 25 33 c.p. lamps; engine-room, two arc lamps; pay-boxes, boilers, etc., 10 32-c.p. lamps. Total, 22 arc lamps, 110 32-c.p. incandescent lamps.

The arc lamps in the shafts are arranged as follows: one in centre of dome, four over the lifts, two at the bottom of shaft, one over the passenger staircase, one outside the passenger entrance, one outside the wheel-traffic entrance. The arrangement is the same in both shafts.

The lamps are of Messrs. Paterson and Cooper's well-known Phœnix type, and are arranged to burn two in series on the 110-volt circuit. Every pair of lamps in both shafts are controlled by switches on the main switchboard, although there are one or two other subsidiary switches placed on the starting platform under the control of the man in charge of the lifts.

The 10 mains for the arc lamps in the north shaft run under the floor of the passenger tunnel in a 3in. iron pipe, this pipe, as before mentioned, being filled with a preparation of resin oil. The oil-insulated mains in both shafts run to a terminal-box placed about 12ft. above the ground level on the side of the shaft; from these terminal-boxes ordinary 600-megohm vulcanised rubber-covered cables fixed on porcelain insulators run to the various lamps. In the foot tunnel the 50 lamps are arranged along the centre line, every alternate lamp being entirely on a separate circuit. In the wheel tunnels they are arranged alternately on either side.

The lamps in both cases are fitted in heavy enamelled cast-iron fittings with brass front and flint glasses, the whole made watertight with a rubber washer. These fittings have special joint-boxes of malleable iron attached to them through which the main pipes run, a specially-packed gland being fitted close to the lampholder to keep back the oil. Special bends, fuse-boxes, etc., are fitted to meet the requirements of the special form of insulation used. The cables being covered with a very absorbent material, great care had to be taken in getting the cable into the pipes that they were free from all moisture.

The whole of the installation was designed and carried out under the direct superintendence of Mr. E. George Tidd, A.I.E.E, A.M.I.C.E., Messrs. Paterson and Cooper's engineer and manager for Scotland.

ON A METHOD OF DETERMINING THE THERMAL CONDUCTIVITY OF METALS, WITH APPLICATIONS TO COPPER, SILVER, GOLD, AND PLATINUM.*

BY JAMES H. GRAY, M.A., B.SC.

Communicated by LORD KELVIN, P.R.S.

Of the different methods hitherto employed for the determination of thermal conductivity of metals, only those which were elaborated by Forbes and by Angström have been successful in giving absolute results with fair approach to accuracy. The two methods, in the hands of these and subsequent experimenters, have given closely concordant results, both for copper and for iron. They, however, possess the disadvantages of being exceedingly elaborate, requiring, as they do, very extensive preparations and comparatively large masses of the metals which are to be tested. For this reason only the less costly metals can be tested, as it would be impracticably expensive to obtain a bar of gold or platinum, for example, a metre or more in length, and perhaps two square centimetres section.

The method used in the present investigation (for which a grant of £50 was obtained from the Government Research Fund) is free from these objections. It was suggested by Lord Kelvin as far back as 30 years ago, about the same time that the late Principal Forbes began his experimental enquiry as to whether thermal conductivity varied with temperature. The chief advantages of this method are that (1) it is much simpler than the others; (2) a test of the conductivity of any metal can be made in two or three hours; and (3) (perhaps most important of all) only a few grammes of the metal are necessary. Thus, even the rarest and most expensive metals can be tested at very moderate cost.

The method is essentially the experimental realisation of the theoretical conditions implied in the fundamental formula—

$$Q = k\, A \frac{v - v_0}{l} t,$$

where the symbols have their usual meaning. The metals to be tested are made in the form of wires of circular section. One end is kept at a constant temperature, v, and the flow of heat, Q, in a given time, t, is measured. The length and section being known, all the data are obtained for the determination of the absolute value of the thermal conductivity. It will be noted that this value is the proper mean conductivity corresponding to the range of temperature between the ends of the wire.

Fig. 1 is a perspective drawing of the apparatus which has been used in the tests of this method. Fig. 2 is a section (all the parts being drawn quarter full size) containing the axis of the wire to be tested. Fig. 3 is a section, drawn full size, through the middle of the apparatus, in a plane perpendicular to the section in Fig. 2, and showing in greater detail the wire, calorimeter ball,

* From the *Philosophical Transactions* of the Royal Society of London.

Digitized by Google

and that part of the heating-box at which the wire is soldered.

Referring to Fig. 2, W is the wire to be tested. The upper end of W is soldered into the bottom of the copper box, B, and the lower end into the solid copper ball, C, the diameter of which is 5·5cm. The sides of the copper box, B, are of thin sheet copper, and the bottom of copper, 3mm. thick. B is supported at the middle by being fitted

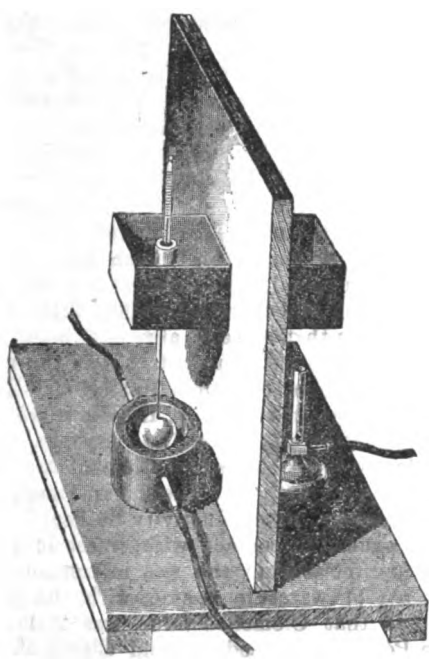


FIG. 1.

into a rectangular hole in a wooden screen, L, of dimensions 60cm. × 60cm. by 2cm. thick. In the hole of the copper block, K, a small thermometer is inserted for measuring the temperature of the other end of the wire. The box, B, is filled with water, and kept boiling briskly. The ball, C, is the calorimeter by which the amount of heat conducted by the wire, W, is measured. In order to measure the temperature of C, a very sensitive thermometer, which can be

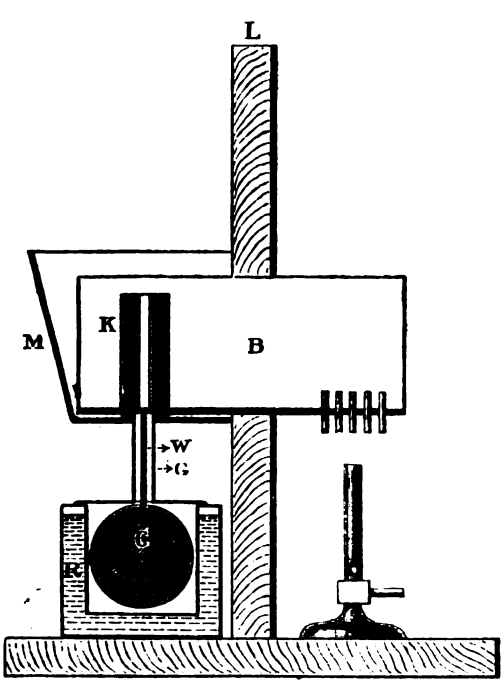

FIG. 2.

read to one-fortieth of a degree C., is inserted in a hole drilled in C. This hole reaches to a depth of 3·6cm. from the circumference of the ball. The bulb of the thermometer in the ball is surrounded by water or mercury. Surrounding the heating-box, B, is an asbestos covering, M, to prevent heat from reaching the calorimeter from the sides of the box. In order to keep the temperature of the air surrounding the calorimeter constant, the latter is surrounded by a water-jacket, R, through which water at the temperature of the air is kept circulating. This water-jacket is simply a cylindrical vessel, made of copper, with double walls, between which the water circulates. The inside diameter is about 1cm. greater than that of the ball. The top of the water-jacket is covered with three or four layers of paper, so that the air surrounding the ball is completely separated from the outside air, and is kept at a constant

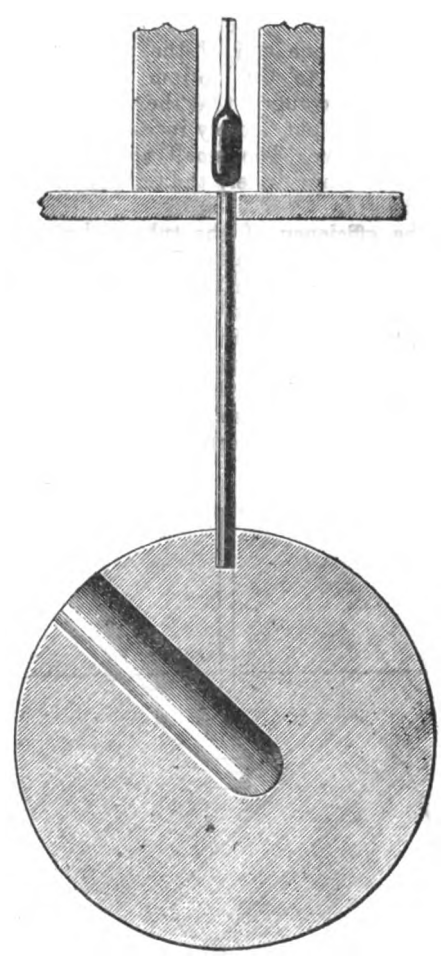

FIG. 3.

temperature. Surrounding the wire, all along its length, is a tube of cardboard, G, of inside diameter 1cm. Between the wire and the inside of the tube cotton wool is loosely packed, so as to prevent, as effectually as possible, circulation of air about the wire.

From Fig. 2 it will be seen that the heat from the Bunsen is prevented from reaching the wire or the ball by the wooden screen, L. In the bottom of the box, just above the Bunsen, are riveted a number of copper pins, so as to catch and distribute the heat of the burner. Fig. 4 shows a plan of the box.

It will be convenient to classify the sources of error that may affect the results, and to deal with them at this point: (1) There is, unless proper precautions be taken, loss of heat due to radiation from the surface of the wire, and therefore the value obtained for the conductivity will be too low. (2) The temperature indicated by the thermo-

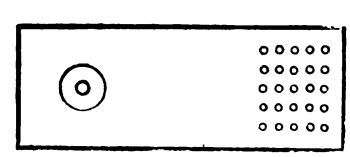

FIG. 4.

meter in the hot water may not be the same as that of the end of the wire at the point where it enters the box. Also, the temperature of the ball may not be the same throughout. (3) The thermometer may not indicate the average temperature throughout the ball. (4) There may be a lag in the thermometer. (5) There may be some error due to the solder at the ends of the wire.

1. Loss of heat due to radiation from the surface of the

Digitized by Google

wire. As this was the most obvious source of error, a long time was spent and much work done in investigating it. The cardboard tube, G (Fig. 2), was found to be thoroughly efficient in preventing radiation. It can be very easily made by rolling a long strip of paper, which has been previously gummed on one side, several times round a circular rod of 1cm. diameter. The length of the tube is a little less than that of the wire. After the gum has dried, a slit sufficiently wide to admit the wire is cut parallel to the length. A circular piece of cardboard is fixed with gum to one end of the tube, as a flange for attaching the tube to the bottom of the heating-box. After it has been arranged that the wire is in the central line, cotton wool is put loosely in and the slit closed up with gummed paper. The small volume of air in this tube takes almost immediately the temperature of the wire all along its length.

To test the efficiency of the tube, a large number of experiments was made, the results of which are given further on. It is clear that for a given difference of temperature between the ends, the loss by radiation from the surface of a wire of given diameter will be greater the greater the length. If, then, there be no error which becomes less the greater the length, and thus compensates for the radiation error, a sufficient test of the efficiency of the tube will be to determine the conductivity with

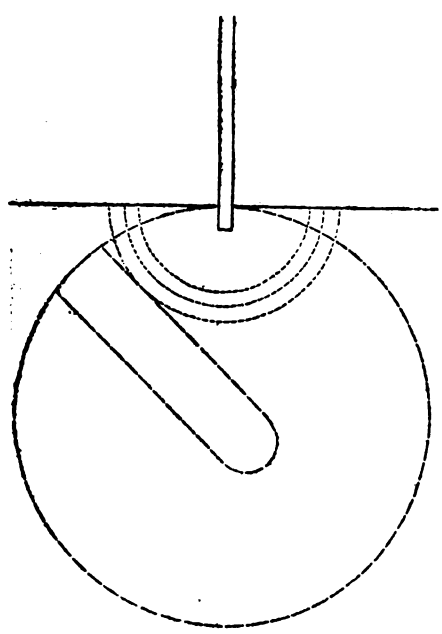

FIG. 5.

different lengths of the same wire. The shorter lengths ought to give a distinctly higher value, since the radiation from the surface is not only less than in the longer lengths, but the quantity of heat conducted along the wire per second is greater, and therefore the percentage error due to radiation rapidly diminishes.

In order to determine a superior limit for the error due to loss of heat by radiation, a calculation is made below. The numbers used are taken so as to be as unfavourable as possible, and give a value much higher than what would practically turn out. In the case of copper wire, the surface was always somewhat tarnished, so the emissivity may be taken as intermediate between those of polished and blackened copper—that is, ·0008. The diameter and length of wire were respectively ·2cm. and 4cm. The temperature at the hot end was 98deg. C., at the cold end 14deg. C. The curve of temperature along the wire being logarithmic, the mean temperature will be considerably less than half the sum of the highest and lowest temperatures, which would assume that the curve is a straight line passing through the highest and lowest points. Take, however, the curve to be a straight line; then the mean temperature above that of the air is 42deg. C. The quantity of heat, Q, lost from the surface, S, of emissivity, E, in one minute, is

$$Q = E S \times 42 \times 60$$
$$= 1{\cdot}91 \text{ C.G.S. units approximately.}$$

The quantity of heat conducted along the wire during this minute, as taken from one of the tests, was $\cdot 5 \times 68{\cdot}9$, ·5 being the rise in temperature, and 68·9 the capacity of the calorimeter. The maximum percentage error due to radiation in a length of 4cm. is, therefore, 5·5 per cent. This is on the assumption that there is no jacket round the wire, but even then the actual loss would probably be less than 3 per cent. if currents of air be avoided. This rough calculation shows that radiation from the surface of the wire need not be considered as an objection to the method.

2. Possible error due to the fact that the thermometers are not actually at the ends of the wire, and so may not be indicating the proper temperatures. The effect of this error would also be to give too low a value for the conductivity. To guard against this the bottom of the box is made very thick, and the large block, K (Fig. 2), is added so as to hold the thermometer. The difference of temperature between the inside and outside surfaces of the bottom of the box is certainly exceedingly small, if as much heat as the wire can take away is supplied to it. Since the heat is supplied by boiling water, it is, however, possible that the copper conducts so quickly that there is always a layer of water, it may be thin, immediately in contact with the metal at a very much lower temperature than 100deg. C. This point is particularly emphasised by Lord Kelvin in volume 3 of his "Collected Papers," where he remarks upon the exceedingly low values obtained by Clément and Péclet for the conductivity of copper. These experimenters both attempted to measure the conductivity by keeping one side of a slab of the metal in contact with water at a constant temperature and measuring the rise in temperature of a known quantity of water in contact with the other side. The result was that Clément's value was 200 times too small, while Péclet, who tried to avoid Clément's error by having the water violently stirred, succeeded in obtaining a value six times too small. With the large surface to carry away the heat, Péclet's method is useless for any substance having so high a conductivity as even the worst of the metals, since the stirring could never be rapid enough without introducing fresh complications. The direct tests applied to determine this error in the present investigation showed that the temperatures on the inside and outside of the bottom of the box were the same.

The following approximate calculation serves to show the order of magnitude of the error due to the assumption that the thermometer in the ball indicates the temperature of the end of the wire. It is clear that the difference of temperatures between the wire where it enters the ball, and the thermometer will be much less than that found as follows: Take the case of a wire carrying heat to an infinite block of metal whose surface is plane, and remark that the isothermals in the block would be hemispherical surface (Fig. 5) having for their common centre the point where the axis of the wire enters the ball, and suppose the flow of heat to be steady.

Let K = conductivity of the wire;
k = " " ball;
a = radius of the wire;
b = " " ball;

Then the quantity of heat that flows through any hemispherical surface distant r from the end of the wire is

$$Q = -k \frac{dv}{dr} 2\pi r^2;$$

and, since the flow is steady,

$$\frac{d}{dr}\left(-k \frac{dv}{dr} 2\pi r^2\right) = 0.$$

Hence $$r^2 \frac{dv}{dr} = C_1,$$

which gives $$v = C_1 r^{-1} + C_2.$$

For $r = a$ let $v = V$, and for $r = b$ let $v = \theta$.

Hence $$v = a\,b \frac{V - \theta}{b - a} r^{-1} + \frac{\theta b - V a}{b - a},$$

whence $$-\frac{dv}{dr} = ab \frac{V - \theta}{b - a} r^{-2};$$

and $$Q = 2\pi k \frac{V - \theta}{b - a} a\,b.$$

Digitized by Google

Also $$Q=(V_1-V)\frac{\pi a^2 K}{l}$$

where V_1 is the temperature at the hot end of the wire, and l the length of the wire.

Since V is the temperature of the wire just where it enters the ball, and θ the temperature at the centre of the ball, $V-\theta$ is certainly much greater than the error, a superior limit to the magnitude of which we wish to ascertain. The heat which flows through the wire must be equal to that which flows into the ball; therefore

$$(V_1-V)\frac{\pi a^2 K}{l}=2\pi k\frac{V-\theta}{b-a}a\,b;$$

whence $$V-\theta=(V_1-V)\frac{a}{2l}\frac{K}{k}\frac{(b-a)}{b};$$

$$=-(V-\theta+\theta-V_1)\frac{a}{2l}\frac{K}{k}\frac{(b-a)}{b};$$

and, therefore,

$$V-\theta=(V_1-\theta)\frac{\frac{a}{2l}\frac{K}{k}\frac{(b-a)}{b}}{1+\frac{a}{2l}\frac{K}{k}\frac{(b-a)}{b}}.$$

In this case $V_1=100$deg. C., $\theta=15$deg. C., and, since the copper of the wire and ball were the same, $K/k=1$; $b=27$mm., $a=1$mm.

Take $l=8$cm.; then

$$V-\theta=85\,\frac{\frac{1}{160}\frac{26}{27}}{1+\frac{1}{160}\frac{26}{27}}\doteqdot\cdot5\text{deg. C.}$$

Take $l=3$cm., which is less than the shortest length used;

then $$V-\theta=85\,\frac{\frac{1}{60}\frac{26}{27}}{1+\frac{1}{60}\frac{26}{27}}\doteqdot1\cdot3\text{deg. C.}$$

Therefore 1·3deg. C. is greater than the extreme possible error made with the copper wire—that is, 1·3 in 85, or about 1·5 per cent.

Several attempts were made to obtain a direct test of this by applying a thermo-electric junction to the wire just at the point where it entered the ball. Owing, however, to the large mass of the ball which had to be heated, it was found most difficult to solder the thin wires of the theremo-electric junction at the required place, and, after several unsuccessful attempts, it was given up, as the indirect proof supplied by using different lengths of wire seemed quite satisfactory.

3. The thermometer in the ball may not indicate the average temperature. This also would be tested by using different lengths of wire, and, as will be seen, the results show that there was no substantial variation.

4. Lag in the thermometer which measures the rise in temperature of the ball. Here again different lengths will be a test. Also, in case that the water round the bulb of the thermometer caused the lag, mercury was substituted, but no difference in the result was obtained.

5. The solder at the ends did not cause any difference of value for different lengths. The method of conducting a test is as follows. Take a length of not more than 8cm. of the wire. As it is very easy to obtain any diameter, it will be convenient to have a hole bored in the bottom of the heating-box, just below the thermometer, of diameter rather more than 2mm., and depth 3mm. or 4mm. The heating-box must be brazed together, otherwise it is apt to fall to pieces when the wire is being soldered in. The latter process can be done with ordinary solder. The mass of copper in the box being considerable, it is rather a troublesome matter to solder the wire into it, as the whole box has to be heated. For this reason a soldering iron cannot be used. The box is most easily heated by a blow-pipe flame and the wire then inserted. The extra solder is then cleared off, so as to give a definite point from which to measure the length. After this end is fixed, the other end is soldered in a similar manner to the copper ball, and in the latter case fusible solder melting at about 100deg. C. will do quite well.

It was, however, found that the method of soldering just described, and used in this investigation, was very troublesome, and required some practice. If new apparatus were being made, it would certainly be much more convenient to make an alteration in this respect. The following plan would make the soldering of the wire a very easy process, instead of, as described, a difficult one. Six copper plugs, each of the shape shown in sectional elevation and plan in Fig. 6, might be made, 8mm. in length and 1cm. diameter, so as to screw into a corresponding hole in the bottom of the heating-box; and six similar plugs might be made for the ball. In each of the plugs the central hole might be made of a different diameter, varying from 2mm. to 4mm. In this way, wires of different diameters could very easily be soldered into the suitable plugs, which could then be screwed, first the one end into the ball, then the other end into the box. The two side holes shown in Fig. 6

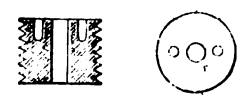

Fig. 6.

are for the purpose of facilitating the screwing in of the plugs. By screwing into the ball first, the possibility of twisting the wire is avoided. It is advisable not to use wire of diameter much less than 2mm., for, in wires of less diameter, the length required to give a readable rise of temperature per minute becomes inconveniently small, unless the calorimeter ball is made very small.

(To be continued.)

TRANSMISSION OF ENERGY BY THREE-PHASE CURRENTS WITH DOUBLE TRANSFORMING.

M. Julien Lefèvre has an article with this title in *L'Electricien* of June 8. He says although the use of multiphase currents is tolerably recent, there have already been a fair number of industrial applications of the system. The Compagnie de Fives-Lille has adopted three-phase currents for the transmission of energy. The dynamos producing these currents are not of any special design: they are of the same system as those of the Lauffen-Frankfort installation. They can be constructed for high-tension currents, but the company recommends rather the employment of low-tension machines, together with transformers. Thus the generator at the Lyons Exhibition gave 32,000 watts, at the speed of 750 revolutions a minute, with a frequency of 50 and a pressure of 120 volts between each principal conductor. The current thus produced is transformed up for transmission purposes, and reduced to low tension, on arrival, by a second transformer. As the transformers have a very high efficiency, the loss which results from this double transformation is insignificant. The transformers used consist of three vertical coils, the iron cores of which are connected at each end by yokes. Their magnetic circuits are thus closed, although only having one bobbin for each current, for each core serves as a return to the lines of induction of the other two. These apparatus do not take up much floor-space. In small types the two windings are superposed. From 60 kilowatts upwards each circuit is formed of coils in sections coupled in quantity for low tension, in series for high tension. The coils of the two windings alternate on the core and are carefully insulated by mica. The machine shown at Lyons was of 10 kilowatts, and designed to transform a pressure of 100 volts into one of 2,000 volts, and conversely. At the arrival station, the three-phase currents, after being converted to 100 volts by the second transformer, can operate special motors. The magnets of these apparatus have three sets of coils, producing a revolving magnetic field; the core of the armature is traversed by a series of copper bars, joined at each end by a copper ring. The Compagnie de Fives-Lille, in the installations which it carries out, feeds a number of small three-phase current motors from the lighting circuit.

COMPARISONS.

Comparisons are odious, as we all know, but they have been made, are being made, and will be made, whatever may be said to the contrary. Comparisons are the sellers' stock-in-trade, and almost always misleading. Whatever arguments may be advanced against comparisons will have no practical effect, for usually the listener understands nothing of the technicalities of the subject under discussion, and has to accept the data to be compared from the speaker—generally, the would-be-seller. If the professor and the theorist only knew their business thoroughly, they would long ere this have provided almost every industry with standard theoretical data, together with standard practical data—the latter of which the practical man might hope to reach, the former never. Btween the theoretical and the practical a wide gulf lies—totally impassable. The seller buttonholes his man or his men and declaims volubly about what has been done by himself or his firm at so-and-so, carefully steering clear of the conditions that may exist at the place under discussion militating against so great a percentage of success, but pressing forward those conditions that tell in favour of his argument. We suppose it is almost or quite impossible to get an unbiassed authority to draw up standard data in certain directions for the purposes of comparison. To take a question only indirectly affecting the electrical industry where such data would seem to be easily obtained. We refer to the calorific value of refuse. In our last issue we had a paper on this subject, and the results there given differ so widely from those of other experimenters that at the meeting where the paper was read and discussed the want of standard data was referred to by several speakers. Last autumn the results of some experiments in refuse destruction gave a calorific value for the refuse greater than that of the best Welsh steam coal. Surely in this case it is not impossible to get standard data with which to compare results. Take the one figure—the average moisture of refuse. Is there no society or institution that can or will obtain this information? Then, again, what should be the temperature in the furnace? Is 1,200deg. F. sufficient, or is the work better done with 1,800deg. or 2,000deg.? What really is the temperature to be aimed at? We suggest that the Association of Municipal Engineers form a sub-committee to tabulate standard data with regard to refuse destruction. Then we should know the temperature of the gases leaving the furnace, and have some idea of how far this temperature could be degraded for utilisable purposes. Coming to something more directly interesting to electric light consumers, we may refer for a moment to the replacing of lamps. Why should canvassers hide the fact—or, rather, neglect to mention the fact—when touting for orders that a by no means negligible part of the cost of electric lighting will be found to consist of lamp renewals. A user of the electric light said the other day: "We have been greatly disappointed; we thought the lamps were practically everlasting, and no one indicated the contrary to us." What is a fairly good standard for lamp renewals? What, in

Digitized by Google

fact, should users expect in this direction? Surely, it is best to be quite clear on this matter rather than to blur it over and allow opposing interests to intimate that electrical people are afraid of the truth, and wilfully keep back certain information from their customers. If we look in another direction, such as railway work, it will be found that engineers have tabulated results for many years, and may claim to have standard data with regard to the lasting properties of every part of a locomotive. They can tell you what should be the annual cost of maintenance of each item. We cannot see why electrical engineers should fear to give similar information. It has over and over again been cast in our teeth that we do not dwell lengthily upon the details of failures. It is not our place to do so, but the tabulation of failures and a general discussion upon failures would be of great value. Referring back to the question of lamp renewals. The customer ought to know that renewals are inevitable. He ought also to know the average cost of such renewal of particular lamps under his own running conditions, and the seller of electrical energy should be able to furnish that information. It may be said that such information means definite patronage of certain makers. Why not? Is there any hesitation about the wine merchant, or the glover, or the tailor, or the dressmaker in giving the names of their best wares, and why they deem them the best? What is the course pursued by electrical manufacturers? To the newspapers they say, "We won't advertise if you say your soul is your own and utter a favourable opinion about other folks' wares, or utter unfavourable opinions about ours." They make a trade ring, and the members of the ring scratch each other's backs and push each other's wares. Certainly, comparisons are odious, whether it be in regard to dynamos, systems, or finance. Gradually, no doubt, a better tone will prevail, and neither private consumers nor municipalities will be misled as to costs.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 18.)

7. *Armature Resistance.*—From (31):

$$r_a = \frac{1}{4 \times 21} \times 1{,}075 \times .001144 = .0147 \text{ ohm at } 15{\cdot}58\text{ C.}$$

8. *Useful Flux.*—From (3):

$$\Phi = \frac{6 \times 515 \times 10^9}{2 \times 84 \times 400} = 46{,}000{,}000 \text{ webers} = 46 \text{ megawebers.}$$

9. *Radial Depth, Mean Cross-Section, and Average Magnetic Density of Armature Core.*—Taking a maximum density of 70,000 webers per square inch in the smallest cross-section of the armature core (see Table XVII.), formula (18) gives a radial depth of

$$b_a = \frac{46{,}000{,}000}{2 \times 70{,}000 \times 38 \times .9} = 9\tfrac{3}{4}\text{in.}$$

The maximum depth of the core, b'_a—that is, half the largest chord that can be drawn between the outer and inner core peripheries—can be obtained from Fig. 138:

$$b'_a = \sqrt{14^2 - 4\tfrac{1}{4}^2} = 13{\cdot}4\text{in.}$$

The mean sectional area of the armature core, therefore, is:

$$A_a = (9{\cdot}75 + 13{\cdot}4) \times 38 \times .9 = 792 \text{ square inches,}$$

and the average magnetic density in the armature core:

$$\mathfrak{B}_a = \frac{46{,}000{,}000}{792} = 58{,}000 \text{ webers per square inch.}$$

10. *Energy Losses in Armature.*—From (35) the $C^2 R$ loss is:

$$w_a = 1{\cdot}2 \times 600^2 \times .0147 = 6{,}350 \text{ watts.}$$

The frequency is $N_1 = \frac{400}{60} = 6{\cdot}67$ cycles per second.

The mass of the armature core, from (38):

$$M = \frac{18\tfrac{1}{4}'' \times \pi \times 38 \times 9\tfrac{3}{4} \times .9}{1{,}728} = 11 \text{ cubic feet.}$$

The hysteresis factor for $\mathfrak{B}_a = 58{,}000$, from Table XXIV., is $\eta = 20{\cdot}92$, and the eddy-current factor for $\mathfrak{B}_a = 58{,}000$, and $\delta = .020''$, from Table XXVII., is $\epsilon = .097$; hence the energy losses due to hysteresis and eddy currents, from (39) and (41), respectively:

$$w_h = 20{\cdot}92 \times 6{\cdot}67 \times 11 = 1\,535 \text{ watts.}$$

$$w_e = .097 \times (6{\cdot}67)^2 \times 11 = 47 \text{ ,,}$$

The total energy dissipation in the armature, by (42), is:

$$W_a = 6{,}350 + 1{,}535 + 47 = 7{,}932 \text{ watts.}$$

11. *Specific Energy Loss and Temperature Increase in Armature.*—From Table XXIX., the length of the heads of our armature will be:

$$l_h = .35 \times 28 + 2 \times .8 = 11\tfrac{1}{2}\text{in.}$$

The radiating surface, consequently, from (44):

$$O_a = (28 + 2 \times .8) \times \pi \times (38 + 1{\cdot}8 \times 11\tfrac{1}{2}) = 5{,}550 \text{ square inches.}$$

The pole area being about $30 \times \pi \times 38 \times .8 = 3{,}040$ square inches, the ratio of pole area to total radiating surface is $\frac{3{,}040}{5{,}550} = .55$; and since the peripheral velocity is 50ft. per second, we obtain from Table XXX. a specific temperature increase of $\tau_a = 45{\cdot}5$deg. C. The rise of armature temperature, therefore, will be, by formula (47):

$$t_a = 45{\cdot}5 \times \frac{7{,}932}{5{,}550} = 45{\cdot}5 \times 1{\cdot}43 = 65\text{deg. C.}$$

12 *Circumferential Current Density and Running Value of Armature.*—From (49) we obtain

$$\gamma = \frac{168 \times \frac{600}{2}}{28 \times \pi} = 572 \text{ amperes per inch of core circumference.}$$

This value is within the load limit given in Chapter 20; the output of the dynamos under consideration, 300 kilowatts, must, therefore, be within the limit of maximum safe output, which is really the case, for from (53) we obtain

$$W_{max} = 28^2 \times 38 \times .91 \times 30{,}000 \times 400 \times 10^{-6} = 325{,}000 \text{ watts}$$

The running value of the armature is found from (54):

$$\rho = 20{,}000 \times \frac{515 \times 600}{620 \times 30{,}000} = 332 \text{ watts per pound of armature conductor at } \mathfrak{B} = 20{,}000,$$

which is within the practical limits given in Table XXXIII.

II. *Dimensioning of Magnet Frame:* (1) *Total Flux Through Magnetic Circuit.*—From Table LII., the probable leakage-factor of a 300-kilowatt upright horseshoe-type machine is $\lambda = 1{\cdot}20$, and therefore the approximate total flux:

$$\Phi' = 1{\cdot}20 \times 46{,}000{,}000 = 55{,}200{,}000 \text{ webers} = 55{\cdot}2 \text{ megawebers.}$$

2. *Area of Magnet Frame.*—The cores and yoke being of wrought iron, the sectional area required, according to Table LIX., is:

$$A_m = \frac{55{,}200{,}000}{90{,}000} = 614 \text{ square inches.}$$

3. *The Magnet Cores.*—The cylindrical form of cross-section being chosen, the diameter of the magnets is:

$$d_m = \sqrt{614 \times \frac{4}{\pi}} = 28\text{in.}$$

* From the *Electrical World* (New York).

Digitized by Google

The length is obtained from Table LXIV. by interpolation—viz.: $l_m = 35$in. Distance apart from Table LXVIII.: $c = 16$in.

4. *The Yoke.*—The width of the yoke, in the type chosen, is equal to the diameter of the cores; therefore, its height:

$$h_y = \frac{614}{28} = 22\text{in.}$$

The length of the yoke is given by the diameter of the cores and by their distance apart:

$$l_y = 2 \times 28 + 16 = 72\text{in.}$$

5. *The Pole-pieces.*—The bore of the field is found by adding the following items:

Diameter of armature core		= 28·000
Winding	$4 \times \cdot 322''$	= 1·288
Insulation and binding	$2 \times \frac{5}{32}''$	= ·312
Clearance (Table XLVIII.)	$2 \times \cdot 2''$	= ·4
Field bore	d_p	= 30·000in.

Pole distance, from Table XLVII.: $c_p = 5 \times (30 - 28) = 10$in.

In Table LXX. the remaining dimensions of the pole-pieces for the case in question, cast iron being employed, are given as follows:

Height of pole-pieces	$h_p = 30\frac{1}{2}$in.
Length " "	$l_p = 38$in.
Thickness in centre	= 15in.

6. *The Zinc Blocks.*—Table LIV. gives the height of zinc blocks for dynamos of 300 kilowatts capacity and with a 28in. drum armature as $h_z = 11$in.

Fig. 139 shows the field-magnet frame thus dimensioned.

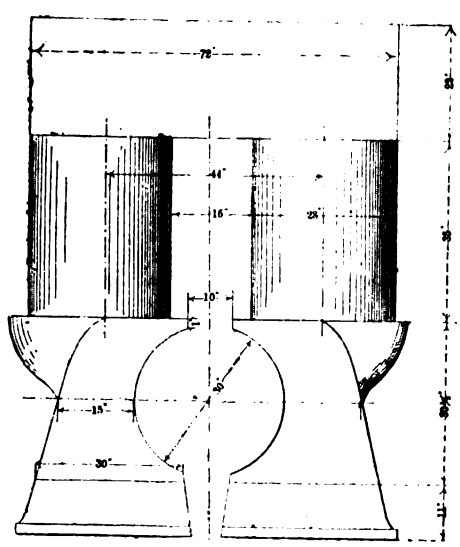

FIG. 139.

III. *Calculation of Magnetic Leakage.*—The permeance of the gap spaces, from (126), is:

$$P_1 = \frac{\frac{1}{4}\left(28 \times \pi + 30 \times \pi \times \frac{141}{180}\right) \times 38}{1{\cdot}30 \times (30 - 28)} = \frac{1{,}540}{2{\cdot}6} = 593.$$

The permeance across the magnet cores, from (129):

$$P_2 = \frac{28 \times \pi \times 35}{2 \times 16 + 1{\cdot}5 \times 28} = \frac{3{,}080}{74} = 41{\cdot}6.$$

Permeance across pole-pieces, by (114):

$$P_3 = \frac{\frac{1}{2} \times \left[38 \times \left(30 + \frac{30\frac{1}{2}}{2}\right) + 900^*\right]}{2 \times 11} + \frac{2 \times 38 \times 1}{10}$$
$$= 59{\cdot}6 + 7{\cdot}6 = 67{\cdot}2.$$

Permeance between pole-pieces and yoke, by (114) and (115):

$$P_4 = \frac{500\dagger}{35} + \frac{38 \times 30\frac{1}{2}}{2 \times 35 + (30\frac{1}{2} + 22)\frac{\pi}{2}} = 14{\cdot}3 + 7{\cdot}6 = 21{\cdot}9.$$

Actual leakage factor, from (110):

$$\lambda = \frac{593 + 41{\cdot}6 + 67{\cdot}2 + 21{\cdot}9}{593} = \frac{723{\cdot}7}{593} = 1{\cdot}22.$$

* Portion of bedplate opposite one pole-piece.

† Projecting area of pole-piece (=area, top of pole-piece—area of magnet core).

The actual total flux, consequently,

$\Phi' = 1{\cdot}22 \times 46{,}000{,}000 = 56{,}000{,}000$ webers
$= 56$ megawebers.

IV. *Calculation of Magnetising Force*: (1) *The Magnetic Circuit.*—The magnetic circuit of our machine consists of four different portions:

Air-Gaps:

Area: $A_g = \frac{1}{4}\left(28\pi + 30\pi \times \frac{141}{180}\right) \times 38 = 1{,}540$ square inches.

Length: $l_g = 1{\cdot}30 \times (30 - 28) = 2{\cdot}6$in.

Density: $\mathfrak{B} = \frac{46{,}000{,}000}{1{,}540} = 29{,}900$ lines per square inch.

Armature Core: Mean density (see above, I., 9): $\mathfrak{B}_a = 58{,}000$ lines per square inch. Specific magnetising force, from Table LXXI.:

$f(\mathfrak{B}_a) = 12{\cdot}2$ ampere-turns per inch.

Mean length of circuit in armature core, see Fig. 140:

$$l_{(a)} = 18\tfrac{1}{4} \times \pi \times \frac{109\frac{1}{2}\text{deg.}}{360\text{deg.}} + 9\tfrac{3}{4}' = 27\text{in.}$$

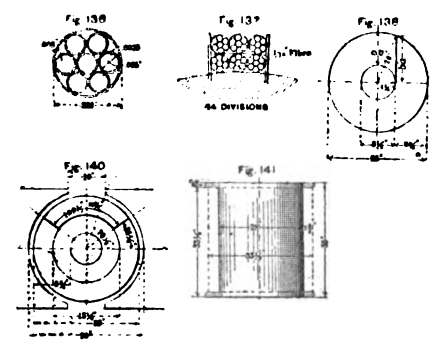
Wrought-Iron Part of Field Frame (Magnet Cores and Yoke):

Area: $A_w = 28^2 \times \frac{\pi}{4} = 616$ square inches.

Length: $l_w = 2 \times 35 + 22 + 44 = 136$in.

Density: $\mathfrak{B}_w = \frac{56{,}000{,}000}{616} = 91{,}000$ lines per square inch.

Specific magnetising force: $f(\mathfrak{B}_w) = 53{\cdot}8$ ampere-turns per inch.



Cast-Iron Part of Field Frame (Pole-Pieces): Least area (in centre): $15 \times 38 = 570$ square inches.

Corresponding maximum density:

$$\frac{56{,}000{,}000}{2 \times 570} = 49{,}200 \text{ webers per square inch.}$$

Greatest area (at pole face):

$$\frac{30 \times \pi}{2} \times 38 \times \frac{141\text{deg.}}{180} = 1{,}400 \text{ square inches.}$$

Corresponding minimum density:

$$\frac{46{,}000{,}000}{1{,}400} = 32{,}800 \text{ webers per square inch.}$$

Average density in cast iron:

$$\mathfrak{B}_c = \frac{49{,}200 + 32{,}800}{2} = 41{,}000 \text{ lines per square inch.}$$

Specific magnetising force: $f(\mathfrak{B}_c) = 93{\cdot}2$ ampere-turns per inch.

Mean length of circuit in pole-pieces: $l_c = 40$in.

2. *Magnetising Forces Required for the Various Portions of the Magnetic Circuit.*—M.M.F. required for gap spaces: $at_g = 0{\cdot}3133 \times \mathfrak{B} \times l_g = {\cdot}3133 \times 29{,}900 \times 2{\cdot}6 = 24{,}400$ ampere-turns.

M.M.F. required for armature core: $at_a = f(\mathfrak{B}_a) \times l_{(a)} = 12{\cdot}2 \times 27 = 330$ ampere-turns.

M.M.F. required for wrought-iron portion of frame: $at_w = f(\mathfrak{B}_w) \times l_w = 53{\cdot}8 \times 136 = 7{,}320$ ampere-turns.

M.M.F. required for cast-iron portion of frame: $at_c = f(\mathfrak{B}_c) \times l_c = 93{\cdot}2 \times 40 = 3{,}730$ ampere-turns.

M.M.F. required to compensate armature reactions:

$$at_r = (k) \times \frac{m \times C}{2} \times \frac{a}{180\text{deg.}} = 1{\cdot}5 \times \frac{84 \times 600}{2} \times \frac{19\frac{1}{2}}{180}$$
$$= 4{,}100 \text{ ampere-turns.}$$

Digitized by Google

Total magnetising force required :

$AT = 24,400 + 330 + 7,320 + 3,700 + 4,100 = 39,880$ ampere-turns.

V. *Calculation of Magnet Winding.*—Magnet winding to be figured to give a temperature increase of $t_m = 20$deg. C. over the standard temperature of 15·5deg. C. Extra regulating resistance at normal load to be 10 per cent. of the magnet resistance.

Radiating surface of magnets, see Fig. 141.

$O_m = 2 \times (28 + 2 \times 2\frac{3}{4}^*) \times \pi (35 - 1\frac{1}{2}^\dagger) = 7,050$ square inches.

The conditions of heat radiation from an electromagnet are similar to those of an armature at rest, with pole-pieces removed; for these conditions, from Table XXX., the specific temperature increase of 75deg. C. for one watt of energy loss per square inch of radiating surface is derived.

The permissible energy loss in the magnet winding, therefore, is found from :

$$W_m = \frac{t_m}{75\text{deg.}} \times O_m = \frac{20\text{deg.}}{75\text{deg.}} \times 7,050 = 1,880 \text{ watts.}$$

The total energy absorbed in the entire shunt circuit (magnet resistance + extra resistance) is :

$$W'_m = 1{\cdot}1 \times 1,880 = 2,070 \text{ watts.}$$

Current flowing through shunt :

$$C_m = \frac{W'_m}{e} = \frac{2,070}{600} = 3{\cdot}46 \text{ amperes.}$$

Number of turns on magnets :

$$T = \frac{A\,T}{C_m} = \frac{39\,880}{3{\cdot}46} = 11,530 \text{ turns.}$$

The mean length of one turn being given by Fig. 141, the total length of the magnet wire is obtained from :

$$L_m = \frac{11,530 \times (28 + 2\frac{3}{4}) \times \pi}{12} = 93,000\text{ft.}$$

The total resistance of the shunt circuit, including the extra resistance, is :

$$r''_m = \frac{e}{C_m} = \frac{600}{3{\cdot}46} = 173{\cdot}5 \text{ ohms.}$$

The magnet resistance alone, therefore :

$$r'_m = \frac{173{\cdot}5}{1{\cdot}1} = 157{\cdot}5 \text{ ohms at } (15{\cdot}5\text{deg.} + 20\text{deg.})$$

or, $= 35{\cdot}5$deg. C.

$$r_m = r'_m \times \left(1 - \frac{t\,\text{deg}_m}{300}\right) = 157{\cdot}5 \times {\cdot}933 = 147 \text{ ohms at } 15{\cdot}5\text{deg. C.}$$

The specific resistance of the magnet wire fulfilling the above conditions is :

$$\frac{r_m}{L_m} = \frac{147}{93,000} = {\cdot}00158 \text{ ohm per foot at } 15{\cdot}5\text{deg. C.}$$

The nearest gauge wire is No. 12 B. & S., having a specific resistance of ·001581 ohm per foot; 93,000ft. of this wire will, therefore, give an actual magnet resistance of :

$$r_m = 93,000 \times {\cdot}001581 = 147{\cdot}1 \text{ ohms at } 15{\cdot}5\text{deg. C.}$$

The total weight of the magnet winding is :

$$lb_m = 147{\cdot}1 \times 12,503 = 1,840\text{lb. bare;}$$

or, $$lb'_m = 1{\cdot}028 \times 1{\cdot}840 = 1,890\text{lb. covered.}$$

The given machine is consequently to be wound with 945lb. of No. 12 B. & S. wire (·081″ + ·008″) per magnet.

The current density in the magnet wire is

$$\frac{6,530}{3{\cdot}46} = 1,890 \text{ C. M. per ampere.}$$

Electrical efficiency of machine :

$$\frac{W}{W + W_a + W_m} = \frac{300,000}{300,000 + 7,932 + 1,880} = {\cdot}968, \text{ or } 96{\cdot}8 \text{ per cent.}$$

If a temperature increase higher than $t_m = 20$deg. C. had been permitted in the field coils, more energy could be spent in exciting the magnets; the shunt current would, therefore, be correspondingly greater and the number of turns correspondingly smaller, resulting in a smaller weight of copper.

* Height of magnet-winding space, from Table LXIII.

† Allowance for core flanges.

EXPERIMENTS ON THE RELATION OF HYSTERESIS TO TEMPERATURE.*

BY FRANK A. LAWS AND HENRY E. WARREN.

This paper gives an account of some experiments to determine the effect of temperatures much above the normal on the dissipation of energy by hysteresis in a specimen of steel.

At the time of the beginning of this research, in February, 1894, there were no complete studies of this subject known to us. A casual reference is to be found in the *Proceedings* of the American Institute of Electrical Engineers, vol. vii., p. 325, 1890, by Prof. Harris J. Ryan. The tests there referred to were made on a cast-iron ring. The maximum temperature employed was 360deg. The details of the measurements are not given. A short paper by Dr. Wilhelm Kuntz appeared in the *Electrotechnische Zeitschrift*, vol. xiii., May 6, 1892. In this Dr. Kuntz showed that the hysteresis loss decreased with rise of temperature. A second paper by the same author appeared in the *Electrotechnische Zeitschrift*, vol. xv., April 5, 1894. The magnetometer method was used by Dr. Kuntz in this work. In this paper tests of several ferrous materials are given, as well as some on a specimen of nickel.

At the outset of this research it was decided that alternating currents should be used, and that the losses should be determined by a wattmeter, thus reducing the time required for observations to a minimum. The instrument which we designed and used we decided to call a watt-balance. Mr. A. E. Kennelly has given in the *Electrical Engineer*, December 21, 1892, a description of a "Differential Wattmeter." This instrument gives the difference of the mean values of two definite integrals representing the primary and secondary energy in a transformer—that is, the losses. The watt-balance measures the ratio of the mean values of two definite integrals. It can therefore be used to measure the efficiency of a converter, giving the result by a single reading.

The watt-balance consists of two electrodynamometer wattmeters one above the other. The movable coils are rigidly connected in our instrument by a spiral-wound paper tube, and consist of 100 turns of silk covered German-silver wire, No. 32 B. & S. gauge. The resistance, including leads, is 103 ohms; the diameter of coils 2cm. In series with the movable coils are two adjustable resistances, r_1 and r_2, as shown in Fig. 1. The stationary coils are arranged in pairs; each is 2·3cm. in mean radius, and contains 130 turns of No. 12 cotton-covered wire. They are movable along their axes, so that the factor of the instrument may be adjusted. The vertical distance between the two dynamometers is 30cm. The movable parts are suspended by a silk thread inside a narrow paper tube to prevent disturbance by air currents, and directive force is given by four spiral springs made of copper wire 0·005cm. in diameter. These springs serve as leading-in wires for the movable coils. The instrument is read by a telescope and scale.

In Fig. 1 is shown the scheme of connections for a hysteresis test. At the left the slide resistances for controlling the currents are shown. By the proper insertion of the connection, C, either a direct or an alternating current could be sent through the remainder of the apparatus, which in the main circuit consisted of an electrodynamometer, one pair of stationary coils, the specimen under test, a known resistance, R, of German-silver strip immersed in kerosene oil to keep it at a constant temperature, and the second pair of fixed coils. At one terminal of R a connection was made by means of a short piece of stout wire and a key, K; beyond the key the circuit branched, passing through the adjustable resistances, r_1 and r_2, the proper movable coils, and returning one lead to the external terminal of the specimen, and the other to the corre-

* Contributions from the Physical Laboratory of the Massachusetts Institute of Technology to the *Proceedings* of the American Academy.

Digitized by Google

sponding terminal of R. The resistance r_1 was some hundreds of ohms, seldom falling below 300, and was more frequently in the neighbourhood of 1,000; r_2 was kept at a constant value, 976 ohms. The resistances, r_1 and r_2, were ordinary plug-boxes, and the assumption was made throughout the work that the resistances of circuits r_1 and r_2 were so high in comparison with their inductances that no correction factor need be applied to the indications of the watt-balance. It may be well to mention that the use of high resistances constructed in the usual way by double winding may lead to serious errors in alternating-current measurements on account of the capacity effects.

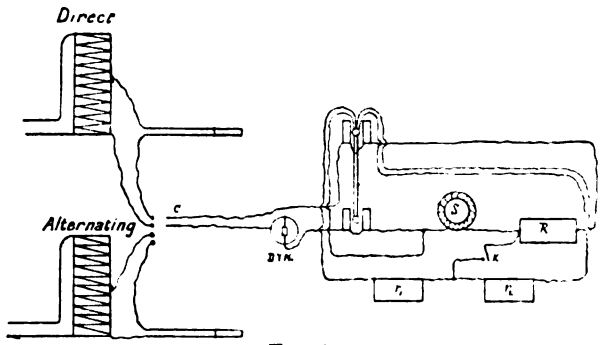


FIG. 1.

If the plug, C, be inserted so that a current flows in the apparatus, and no deflection is observed, then the factors of the upper and lower dynamometers are equal; if the key, K, is depressed, there will in general be a deflection, which may be reduced to zero by adjusting r_1, as a zero reading means that the average values of the products of the currents in the two coils of the upper and lower dynamometers are the same. It is known that the work in S bears the same ratio to the work in R that the total resistance in circuit r_1 does to the total resistance in circuit r_2 If the current is alternating, the work in S is of course divided between hysteresis and heating losses. No allowance has been thought necessary for the work done in the suspended coils. If W_S and W_R represent the work in the specimen and in R, then

$$W_S = W_R\left(\frac{r_1+103}{r_2+103}\right) = \frac{I^2R(r_1+103)}{r_2+103}.$$

I^2 is given by the electrodynamometer D Y N.

To correct for the heating loss in S, a direct current of any convenient magnitude is sent through the circuit, and a second balance, r_1^1, obtained:

$$R = 1{,}079 \text{ ohms}, r_2 = 976 \text{ ohms}; \text{ so } W_S = \frac{I^2}{1{,}000}(r_1 - r_1^1).$$

It will be seen that the watt-balance, as used in the present case, is a wattmeter with an electrodynamic control. The advantage derived from obtaining this control by shunting a portion of the main current is that any manipulation of the circuits does not disturb the equilibrium of the instrument, and that it renders it possible to use the instrument in a null instead of a compensation method.

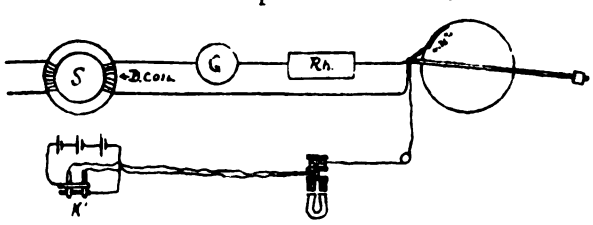

FIG. 2

As the hysteresis loss is a function of the maximum magnetisation, denoted by B, it was necessary to provide some means by which the maximum might be kept constant, and its value determined. The device sketched in Fig. 2 was used for this purpose. In addition to the magnetising coil, the specimen was provided with a winding of 24 turns, which was connected in series with an adjustable resistance of 874 ohms during the tests and a galvanometer of 126 ohms. Leads were carried to the dynamo-room, and terminated in brushes which rested on the edge of an ebonite disc 11in. in diameter fastened rigidly to the dynamo shaft; the brushes were carried by a radial arm, the motion of which is controlled by a small magneto-motor driven by three Leclanché cells. The motor was governed by a reversing key in the testing-room, about 100ft. away. The alternator used had 10 poles, thus making the length of a wave 72deg. A piece of brass, 36deg. or one-half a wave long, was set into the edge of the disc, and the whole carefully trued up. When the dynamo was in action the B current was closed once during a revolution, and for a time corresponding to one-half a wave length. The galvanometer then performs the operation—

$$\frac{2}{T}\int_{t^1}^{t^1+\frac{T}{2}} C\,dt$$

1,500 times a minute. The value of this integral will be a maximum when it extends over the time between + B and − B. By the use of the key, K^1, the brushes may be shifted, and the reading of the galvanometer brought to its greatest value. With the dynamo running at its normal speed a Leclanché cell, E.M.F. 1·4 volts, was inserted in the circuit; R h was 1,374 ohms, and the deflection 21·2 cm.; with brushes short-circuited and R h equal to 14,874 ohms the deflection was 21·8 cm., the ratio of deflection being ·972. If the brushes made perfect contact, and there was no self-induction effect, the ratio would be unity, the entire cycle of operation being performed in a time short compared with the period of the galvanometer. During the tests the reading with R h = 1,374 was frequently repeated in order that the brushes might be kept in as uniform a condition as possible.

Owing to the manner in which the specimen is constructed, the area included in the B winding is but partially occupied by the iron. In calculating the approximate values of B no allowance has been made for this, as the permeability is high in the cases where B has been determined. If observations were taken at temperatures where the permeability was very low, it would be necessary to apply a correction for this unoccupied area. The values of B were calculated by the formula—

$$B = \frac{E^1 R D}{20 A N n R^1 D^1}$$

D is the deflection corresponding to the value of B to be found; R is the resistance in circuit R h; N, the number of turns on B winding; n, the number of revolutions per second; A is the area of the iron included in the B windings; D^1 is the deflection of the galvanometer when an E.M.F. of magnitude E^1 and a resistance R^1 are inserted in the circuit R h, the dynamo turning at the normal rate.

(To be continued.)

SOME PRACTICAL HINTS IN DYNAMO DESIGN.*

BY GILBERT WILKES.

When the matter of this lecture first came up for consideration I thought I would discuss generally the results in relation to designing drawn from my shop experience. I had not, however, gone far when I realised that this subject would cover a number of lectures, so it was limited to refer to continuous-current machines for general purposes. Not only are alternating-current machines designed on very different lines from continuous-current dynamos, but that large and varied class of machines used for traction purposes, and represented principally by the street-car motor, is, I believe, an equally distinct class. The design of street-car motors brings in so many points that place in the background the rules for ordinary designing that the one is little guide to the other.

Street-car motor design is, or should be, more the result of reasoning, based on actual personal experience on a car and under it in the pit, than that of hours and days at a desk. The rules for shafts and bearings for stationary machines are of little use here, and some of the most successful street-car motors are machines of poor electrical design. One I recall has a magnetic leakage of 35 per cent. The real power for continuous work is never equal to the rating of a street-car motor, and the method of control has much to do with the average possible work obtainable without overheating. I have therefore limited my subject to stationary machines—generators and motors for standard work, with special reference to medium-sized machines—neither very large nor very small.

* From the *Bulletin* of the University of Wisconsin.

Digitized by Google

The first thing to be considered is—and this really comes before the actual work of designing—What is absolutely necessary in any good dynamo? In order to compete with other machines on the market, a few points are absolutely essential. These points are to influence the design, but no trimming can be allowed upon them, and to them all considerations of economy, weight, size, and appearance must bend.

The first of these preliminary requisites is mechanical stability, and whether the type is to be the horseshoe or inverted horseshoe, bipolar or multipolar, iron-clad or Manchester, whether the armature is to be smooth or slotted, the same remarks will apply. Let not economy or a bearing of trimmer appearance dictate the use of a small shaft. This is a point in which electrical engineers are systematically criticised by their mechanical brethren. Dynamo shafts are too often on the wrong side of safety. This error is probably an heirloom to us from the time when the generation of electricity itself was so puzzling a conundrum that all other questions were relegated to the background.

I remember one of the first dynamos that I saw—about 11 or 12 years ago. The dynamo-room (which was on board ship, where every square foot is valuable) was large and contained a remarkable tangle of belting and jackshafts, which would be considered ridiculous to-day. The dynamo ran, however, and the lamps gave light, thus answering the most rigorous requirements of the time, until one evening the pulley was wrenched completely off with the end of the shaft. I once heard a complaint from the business side of a company against the large-sized shaft of a large new dynamo. The answer was, "Did you ever hear anyone complain in buying an engine that the shaft was too heavy?" The machine was a success, and the only comments afterwards made about the shaft (which was 5½in. for 150 kilowatts) were to the effect that it was according to common sense.

Let the shaft run in good solid bearings, supported on a solid base. Whether the machine is mounted on skids or the more expensive sub-base, give it a broad foothold. Do not let the weights overhang the extreme points of support like the balls on a balancing pole. The side pull of the belt with a high centre line of shaft will tend to tip the machine, and the changes in the pull due even to the undulations of the belt will cause a tremor in the machine. You may feel it with the hand, and think it a matter of no importance. But each tremor jars the brushes, and in weeks the effects may be visible on the commutator, while in months the foundation may be shaken to pieces. Let your work be such that when it is completed and accepted you have heard the last of it. The dynamo is here to stay. It is to-day as reliable as a high-grade engine, and not one-tenth of 1 per cent. as dangerous.

One does not have to look back many years to the time when each new plant was rather expected to turn in reports of burned-out armatures or fields, when a new street-railway plant might burn out armatures actually by the dozen. But now if an armature is lost in a generator, it is the cause of close enquiry. Not quite so good a record, however, can be shown by most companies in the matter of the armatures of street-car motors. A record of 10 per cent. of the armatures burned out on a new street-railway line in the first three months is not bad.

After the mechanical features comes absence of spark at the brushes. A dynamo minder has no patience with a machine that sparks, and his disgust is soon transmitted to his employers, so that the machine is in disfavour. It is worse than giving a dog a bad name. A large part of the electrical *personnel* is still migratory, and a machine's reputation travels fast.

It is not too much now to expect absolutely no sparking at the brushes under practically constant load, and none under a change either way of 50 per cent. of full load. In fact, the best machines will stand sudden changes from no load to full load, and *vice versâ*, without sparking. If you have ever watched a 20in. belt when opening and closing the snap switch which controls the full load of a 150-kilowatt generator, you will realise the enormous mechanical and electrical strains a good machine must be made to stand for exigencies really as severe as this not infrequently occur in the operation of railway plants. However, my remarks are not intended so much in relation to these larger machines as to the smaller sizes. There are few firms manufacturing dynamos of 150 kilowatts or greater capacity, and therefore the competition is not so severe, and greater freedom is allowed the designer of the large units.

In a visit to the first Edison central station in Pearl-street, New York, one could not look at the hot scored commutators, and see the evidence of excessive wearing, without being almost forced to the conclusion that the generation of electricity and the destruction of copper went hand-in-hand. But this was in the days of Edison's Jumbos—strange to say these first large generators were direct driven—while everyone now knows, in contrast, the beautiful Edison dynamos of later times. In fact, until the last few years, the history of the constant-pressure dynamo in this country is largely a record of Edison's great work. Now even his name does not appear on any dynamos that are on the market.

The commutator of a modern stationary machine will last for years, and often will run, with a proper arrangement for collecting the current, for more than a year without even being turned down.

The brushes and brush-holders must be simple, and should be preferably automatic in taking up wear. Opinion is divided as to the proper material for brushes, and the largest makers seem to prefer copper in some form for large-current machines. Carbon is, however, much easier on the commutator. Brushes of carbon and their brush-holders can be designed which will take off the current just as well as those of copper, and cost no more. The commutator, however, brings in an additional cost where carbon brushes are used.

Considerable prominence was given last year to a device for preventing the shifting of the neutral point by a special arrangement of the series field. The particular form of machine which I have seen illustrated was of what is commonly known as the continental type. I did not see the particular machine, but, from considerable experience with this type, I believe that the dynamo would, if properly designed, work equally sparkless when built as an ordinary machine. I have designed a full line of these machine from 5 to 45 kilowatts. The brushes of any member of the series may be rocked fully 30deg. on each side of the horizontal plane without any sign of sparking, and the lead never changes with the load.

All makers agree in setting about the same limits for heating. The armature is usually not allowed to go above the temperature of boiling water. Occasionally, in order to get more money for a given amount of iron and copper combined in a determined form, a company will increase the ratings of its machines, but loss of reputation and a few burned-out armatures usually have the effect of cooling their ardour and later—the machines. Owing to the effect of the large mass of the field, the temperature of the outside of the coils is never that of the hottest part of the wire, as can readily be seen by bridge measurements. It is, therefore, good practice to run the fields about 15deg. centigrade, as shown by the thermometer, cooler than the armatures. Many formulæ are given for determining the armatures and the fields for a given heating and output, and these often do not agree. But I fancy that much of the disagreement lies in the different forms of fields, different ends to the armatures, and different methods of heading up. Most of the formulæ for field heating take no account of the fact that there may be more cooling by conduction through the iron of the magnet cores than from true radiation. The only safe rule is to learn the constants for a particular type of machine by experiment and make your own empirical standards. Even the heating in different sizes of the same type will vary somewhat from the usual coefficients.

The last point to be considered before commencing upon the specific design of a machine is the bearings. The leading manufacturers use a ratio of length to diameter of bearing varying from 3 to 4½, the usual ratio being about the mean of these figures. The English seem to use shorter bearings than we, and, judging from recent articles in English publications, the self-oiling and self-aligning box is rather new with them. In this country a dynamo cannot go on the market as a high-grade machine without this very desirable feature.

Having thus outlined the considerations which hold good with any high-grade dynamo, we can consider the questions which must receive attention in the designing proper. The most important of these is economy of manufacture. Thirteen years ago it did not matter if the field cores of an Edison "Z" machine were not only twice as long as necessary, but, in fact, were the cause of a waste of material and efficiency, making the machine both cost too much and require too much power for a given output. At that time few people knew any better, and dynamo building in this country was carried on by only two or three small concerns. The importance of economy had not as yet been felt; machine work was lavished without question. Anything was done to make the dynamo work; then it was sold for a large enough price to cover all shortcomings in economy of manufacture. I had to do with an evidence of this lavishness in expense when an officer in the navy. An Edison "L" machine, a 250-lighter, was installed on board ship in 1882. It towered above me, and naturally had not its sea legs on. In order to keep it upright a heavy bronze brace, weighing from 200lb. to 300lb., was bolted to the keeper and to the ship's deck. There was evidently a determination to prevent any loose magnetism getting away by this route. Yet this needless waste in using bronze never excited remark. Matters are now in a very different condition. Every state—almost every town of over 100,000 inhabitants—has one or more smaller or larger manufacturers of electric machinery up to the size of 75 h.p. The business in these smaller machines is enormous, but the margins of profits are very close. There are probably a dozen different makers whose machines fill the preliminary requirements of a good dynamo. Several of these, with enough others to make about 10, are apt to meet in competition on every contract of considerable size. Large sums of money are invested in the different companies, and, with very perfect systems of com-

Digitized by Google

mercial enquiry, the principal companies are alive to the opportunities of every contract. Every dollar on the selling price counts. Remember that magnet wire costing originally about 18 cents per pound costs double this before it leaves the shop on a completed machine. I will explain this large increase. Different shops have different methods of costing. In some, the cost of the actual amount of raw material required for the finished article is added to the sum obtained by placing a fixed charge per hour for each class of work and keeping account of the number of hours each operation requires. In other shops, to the cost of the raw material is added the actual cost of the labour of the men. To this is also added a proper proportion of the shop salaries and general shop expenses. In either case the result is usually known as the shop cost, and amounts to about the increase already mentioned.

The design of the dynamo must be so perfect in economy that when all these additions—running expenses of the shop, shop salaries, percentage for interest and depreciation of plant, percentage for offices, agents, and commissions, and, finally, the percentage for profit—have been made to the actual bare cost of the labour and material, the price must not exceed that of other reliable makers. Think of this, and you will appreciate how dimes in the original material mount up into dollars in the selling price, and an hour's labour at even 15 cents makes a large difference in the product.

There are several details of design and manufacture on which an hour might be spent exclusively, but I shall touch only briefly on the following: building up the armature core; armature winding; commutator construction; prevention of sparking; the relation of size of armature to output; and the relation of field loss to radiating surface. Each of these subjects is worthy of a separate lecture, and in these days, when a new armature insulator is advertised every month, one ought to be posted on the requisites of a good insulator for this purpose, to keep from being led astray by plausible agents.

Armature Core.—There are a great many different mechanical methods of building up the cores of armatures, varying not only for the drum, Gramme, and Pacinotti types, but also varying in each type. All are, however, built up of thin discs of sheet iron or mild steel, forced together between two substantial heads by means of hydraulic pressure or powerful screw presses, and held tight by through-bolts, nuts, and thread on the shaft, or shrunk collars on the shaft. I have used the last method with success in the case of drum armatures, but great care is necessary to obtain the best Norway iron for the collars to prevent their bursting when contracting on the shaft. There are three methods of preparing the plates for the laminations—first, by pasting paper on one side of each sheet, and then punching out the armature plates; second, by punching the plates from the sheets and separating them with loose sheets of tissue paper in building up the armature; third, by using no separator at all, and relying on the oxide formed in rolling to separate the plates sufficiently from metallic contact. This separation does not need to be of high resistance.

I regret that I cannot now state the difference in heating due to the different methods of construction, but I am now having armatures built up to determine this point. It is usual to turn armature cores and balance them before preparing them for the wire. The turning of course tends to bridge over the insulation between the discs, but it is necessary to make a good mechanical job.

The iron usually used is not less than 14 mils thick, the paper should be not more than one mil. Concerning the thickness of iron, many of the smaller concerns use taggers iron, which is not made in this country, but comes from England. It is only seven mils thick and costs, pound for pound, twice as much as good domestic iron 14 mils thick. The latter therefore commends itself if it is adapted to the purpose. To determine this point I made very thorough tests on 15-kilowatt armature cores built of each, with the result that the heating was with the thin discs 29deg. C. and with the thick 38·5deg. C., when run for three hours at their proper speed and field, the induction of which was 5,300 lines of force per square centimetre. This decided me in favour of the thick iron. There is one unknown factor in armature heating—eddy currents in the core—and this must be determined for each type of machine and kind of iron. A loss equal to that for the hysteresis is a usual figure.

In designing dynamos you will find that you cannot always control all of the quantities as you wish. Thus in the continental type, unless you wish to use very high speeds and have very little torque in the machines as motors, you must use large armatures, and this means low induction, as the fields are of cast iron.

Armature Winding.—Armature winding is like the "15" puzzle. When accustomed to the general plans, you can carry them in your head and will become fascinated with the new ideas that form themselves in intricate curves and cross connections. But fortunately or unfortunately for the inventor, there seems to be little new under the sun in this line, and one is very apt to find his pet scheme only a variation of one of the many diagrams in that little book, entitled "Ankerwicklungen der Gleichstrom Dynamomaschinen," by E. Arnold. It is useless to touch on this very broad subject. I will simply say that the old Siemens-Hefner-Alteneck winding has had its day and is succeeded by a number of symmetrical windings. The Gramme ring is disappearing for four-pole machines and being succeeded by the Pacinotti drum, wound preferably with symmetrical replaceable coils. This substitution, weight for weight and dollar for dollar, increases the output of a machine 15 to 20 per cent. or more, depending upon the size and design.

Commutator Construction.—The commutator is the most vital part of the machine, and too much attention cannot be paid to it. There are dozens of different-shaped bars and modifications of the general way of holding them in place. Great variety of opinion exists as to the amount of insulation to be used between the bars. I have found the thickness of insulation between the bars the sole cause of destructive sparking in a line of machines which otherwise worked well and were cured of this by thinning the mica. What sense is there in putting as much mica between the bars, where there is small difference of potential, as there is between the bars and hub, where there may be at least half the voltage of the machine? I have found in my experience that thinner mica between the bars than is usually used gives better results. The proper amount varies with the number of segments and kind of brushes. The best practice is now unanimous in requiring mica between the bars and at the ends of the bars. This does not refer to the special direct-connected generators, whose conductors also serve as commutator segments. The size of bars and diameter of commutator vary greatly with the kind of brush. On account of economy of operation, automatic adjustment, and small amount of attention required, I prefer the carbon brush for all purposes, except, of course, for special machines either of very high voltage or very great current (as for electrical deposition). I have spent much work and study on the subject of brushes, for carbon brushes have some serious faults, though they are ideal in the matter of wear of commutator, small cost, and the small attention they require. The high specific resistance of the material causes heating in the brushes, and, by conduction, in the commutator. To overcome this, I have tried several plans, such as plugging the carbon with bunches of fine wires; depositing a heavy coat of copper around parts of a brush and then soldering these segments together; building up a brush of two thin plates of carbon with a sheet of copper gauze between and soldering a connection to this gauze. The last promised well, but in the course of a few months the commutators showed cutting, and the plan was abandoned for a simple carbon brush with a flexible lead soldered to the back. Carbon brushes were also tried encased in brass sheaths, but these arced to the brush-holders and stuck. Other plans which I have tried are encasing copper gauze in babbitt, and also making the whole brush of a block of babbitt feed radially. One small machine fitted in this way has been running two years without showing wear either on the brushes or the commutator, but I have not seen the plan succeed with larger machines. The following data give an idea of the comparative size of commutators using copper and carbon brushes. The Edison 45-kilowatt bipolar machine has 52 segments, a brush bearing surface 5 19-32in. long and 6 13-16in. diameter; the same sized machine of the continental type designed by me, using carbon brushes, has 34 segments, with a bearing surface 8½in. long and 9½in. in diameter, or there is nearly twice as much copper in the one using carbon brushes. This is, however, an extreme case, as this is the largest-sized machine that I should recommend building of this type. The brushes are thick and are apt not to bear over their entire surface, and yet it is difficult to sub-divide them. Of course, going into the multipolar type, the brushes for low voltages and heavy current can be made thinner and more numerous. I shall compare these two 45-kilowatt machines again later.

Prevention of Sparking.—The prevention of sparking is such a large subject that it is a pity to touch upon it at all, as it can only be imperfectly discussed. There have recently appeared on the subject a number of papers in the English electrical journals which are worth reading.

Sparking may come from careless attendance, overload, error in design (such as thickness of commutator insulation which is not based on calculation), insufficient number of commutator segments, insufficient carrying capacity of segments, brushes covering too many or two few bars, and instability of the neutral point. I leave out of the above machines of positively bad electrical design that have no neutral point. It used to be considered as necessary for steady, sparkless running under wide variations of load that the field magnets should be saturated and operated well above the knee of the curve of the iron of which they are built. In this I do not agree, and where light weight is no object, I prefer to run lower on the curve—at about the knee—as the magnetism at this point is more unstable, and I think the iron can reply more quickly to changes of magnetisation, and therefore keep the voltage of the machine more constant under rapid variations.

Granting that the machine is not badly designed, the three

Digitized by Google

principal conditions for obtaining a steady neutral point, and therefore the sparkless condition, are: the proper number of commutator segments, a proper ratio between the ampere-turns on the fields and of the distorting coils on the armature, and a proper ratio between the total magnetising force required and that used in overcoming the reluctance of the gap. The first two conditions are inter-dependent. The first is more the result of reasoning from experience with dynamos—not only in the shop and testing-room, but in practice with machines of different designs—than from calculation. The other two are dependent upon the type, and one must make his own empirical formulas from the data of the first tests.

It is the third condition—the proper ratio between the magnetising force required to overcome the gap and the total magnetising force—that shows us why it is so much easier to build a sparkless small dynamo than a large one, for 80 or 90 per cent. of the total magnetising force is necessary to overcome the high gap resistance. The area of cross-section of the gap is not only small, but owing to there being several layers of wire on the armature the length is relatively greater. This also points out one reason why small machines are relatively much more expensive, because relatively so much more copper is necessary on the fields. Thus, a 1-h.p. machine costs about one-twentieth of a 50-h.p., and a 3-h.p. about one-seventh of a 50-h.p. machine.

Going back to the 45-kilowatt continental machine, of which I have already spoken. It is at the head of a list of machines of that type. We would therefore expect its field coils to weigh proportionately less than any others of the series, and, if so, that it should be nearer the sparking limit; also, that the complete machine should weigh proportionately less than the other members of the series and cost proportionately less. All of these points are true. The weight of wire on the field is only equal to that on the similar 20-kilowatt machine. Its speed is 800 revolutions at 110 volts as a motor, and when run at about 35 per cent. above this by weakening the field, the machine is unbalanced, and there appears that peculiarly disagreeable snapping at the brushes. Yet the machine runs at its proper speed with absolutely no lead and no sparking at the brushes. The machine does weigh and cost proportionately less than the other members of the series. Its frame is made entirely of one iron casting, and yet the weight of wire on the armature is practically the same as that on the armature of the 45-kilowatt Edison machine above referred to; the weight of the wire on the fields is less, and the total weights are: Edison, 6,800lb.; continental, 7,625lb. This is a very remarkable result when it is remembered that the Edison machine is of wrought iron, and that a considerable expense is necessary in building it to machine and fit the parts of the field circuit. The two machines run at the same speed. Wrought iron does not necessarily make the lightest machine, nor cast iron the cheapest. The design must be adapted to the material to be used.

The Relation of Size of Armature to Output, and the Relation of Field Loss to Radiating Surface.—Concerning the relation of size of armatures to output, different rules are given by different people, and, in fact, not only will the watts per square inch allowable differ for Gramme rings, Pacinotti and drum armatures, but different armatures of the same type but different size will give varying results. A larger ratio of watts per square inch can be allowed for armatures having a single layer, than for those having several layers of wire. This also holds true for field coils. The wide variation that exists may be illustrated by the fact that Kapp states that in field coils the watts per square inch of radiating surface may be taken between one and four. This would be rather an unsatisfactory basis on which to begin designing. I have found Esson's figures good for a first approximation.

As regards the present field for continuous-current designing, the popular gaze is for the present in the direction of polyphase power-transmission apparatus, so that the time is peculiarly suited for quiet study and advance in continuous-current work. It is not necessary that the idea should be entirely novel. Many of the best plans have failed owing to not being worked out properly. See the toothed armature. Four years ago it was regarded as a thing of the past, and was simply remembered as Pacinotti's pioneer attempt. To-day it has returned in an improved form and displaced everything else for large machines and small slow-speed machines.

Something must be done to cheapen the manufacture of small machines, say, from 5 h.p. down, and my remarks may contain a hint as to one way of accomplishing this. Remember that the gap reluctance in small machines is much greater than is necessary from reasons of good running. Is it not possible to use iron wire for these small machinos both on the armatures and fields? I feel sure it is. The fine wire used on these machines is very expensive, costing more than twice as much per pound as for the larger sizes. I have already built fan motors, even for 500 volts, using iron wire exclusively, and the machines were not larger than the usual run of fan motors of equal capacity. I hope soon to try iron wire on small machines of somewhat greater capacity.

One last remark in relation to experimental machines. Let them be roughly made, for they will be very expensive anyhow. An experimental machine should never be begun until the improvement sought for is well fixed in the mind, and all the calculations are made showing just what the machine ought to do, and every detail drawn out to scale. Drawings are slow, tedious, and expensive, but you can change them, and cannot materially alter the final product when it appears in copper, brass, and iron.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

There has been issued a copy of memorandum stating the nature of the proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (No. 5) Bill. These are as follow:

Bootle Corporation Electric Lighting Order, 1895.—The undertakers under this order are the Corporation of Bootle. The area of supply is the borough of Bootle. The order contains provisions that the Corporation shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions—

(1) For the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public and for ensuring a proper and sufficient supply of energy; (2) for the execution of the necessary works and the breaking up of streets, etc., and the alteration of pipes, etc., under streets; (3) for regulating the manner in which energy is to be charged for and fixing the maximum price to be charged; (4) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works, and for holding enquiries by the Board of Trade as to the causes of accidents affecting the public safety; (5) for the supply, use, certifying, inspection, etc., of meters; (6) for the application of moneys received by the undertakers in respect of the undertaking; (7) for the transfer to any company or person of the powers, duties, and liabilities of the Corporation under the order by means of a deed to be approved by the Board of Trade, upon such terms, and subject to such exceptions and modifications (if any), and for such period as may be specified therein; (8) for the revocation of the order under certain circumstances.

New Windsor Corporation Electric Lighting Order, 1895.—The undertakers are the Corporation of New Windsor. The area of supply is the borough of New Windsor and the Eton urban district. The order contains provisions similar to those referred to in the case of the previous order.

Prescot Electric Lighting Order, 1895.—The undertakers are the British Insulated Wire Company, Limited. The area of supply is the urban district of Prescot. The order contains provisions (1) that the undertakers shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions; (2) for the deposit of a certain sum as a guarantee that the works shall be completed; (3) for the audit of the accounts of the undertaking; (4) for the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of energy; (5) for the execution of the necessary works, and the breaking up of streets, etc., and the alteration of pipes, etc., under streets; (6) for regulating the manner in which energy is to be charged for, and fixing the maximum price to be charged; (7) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works, and for holding enquiries by the Board of Trade as to the causes of accidents affecting the public safety; (8) for the supply, use, certifying, inspection, etc., of meters; (9) for the revocation of the order under certain circumstances. The order also provides for the revocation of the Prescot Electric Lighting License, 1894.

Salisbury Electric Lighting Order, 1895.—The undertakers are the Salisbury Electric Light and Supply Company, Limited. The area of supply is the city of Salisbury. The order contains similar provisions to those referred to, and numbered (1) to (9) in the case of the Prescot Electric Lighting Order, 1895, above mentioned. The order also provides for the revocation of the Salisbury Electric Lighting License, 1894.

Southampton Electric Lighting Order, 1895.—The undertakers are the Southampton Electric Light and Power Company, Limited. The area of supply is the county borough of Southampton. The order provides that the undertakers shall lay down mains and furnish a supply of electrical energy throughout the area of supply on certain specified conditions. The order also contains provisions similar to those referred to and numbered

Digitized by Google

(3) to (9) in the case of the Prescot Electric Lighting Order, 1895, above mentioned. The order provides for the purchase of the undertaking by the local authority within 12 months from the commencement of the order upon terms settled by the order. The order also provides for the revocation of the Southampton Electric Lighting License, 1890.

Windermere and District Electric Lighting Order, 1895.—The undertakers are the Windermere and District Electricity Supply Company, Limited. The area of supply is the urban districts of Grasmere, Bowness, and Windermere, a portion of the district of the South Westmorland Rural District Council, the urban districts of Ulverston and Grange, and a portion of the district of the Ulverston Rural District Council. The order contains similar provisions to those referred to and numbered (1) to (9) in the case of the Prescot Electric Lighting Order, 1895, above mentioned. The order also provides for the purchase by the local authorities of the distributing mains and distributing plant belonging to the undertakers in the respective districts after the expiration of 10 years from the commencement of the order by agreement.

The Electric Lighting Provisional Order (No. 6) Bill refers to the—

Liverpool Electric Lighting Order, 1895.—The undertakers under this order are the Liverpool Electric Supply Company, Limited. The area of supply is a portion of the city of Liverpool and of the Local Government district of Toxteth Park. The order contains a provision that it shall not have any force or effect unless the boundaries of the city of Liverpool are, by a provisional order made by the Local Government Board and confirmed by Parliament during the present session, extended so as to include the urban district of Toxteth Park. The order also contains provisions (1) that the undertakers shall lay down mains in certain specified streets within a period of one year, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions; (2) for the audit of the accounts of the undertaking; (3) for the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of energy; (4) for the execution of the necessary works and the breaking up of streets, etc., and the alteration of pipes, etc., under streets; (5) for regulating the manner in which energy is to be charged for, and fixing the maximum price to be charged; (6) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works, and for holding enquiries by the Board of Trade as to the causes of accidents affecting the public safety; (7) for the supply, use, certifying, inspection, etc., of meters; (8) for the revocation of the order under certain circumstances. The order authorises the Corporation of Liverpool to purchase the undertaking, after due notice, on June 30, 1900, or on June 30 in any subsequent year, or, by agreement, in any earlier year, on certain terms specified in the order. The order also provides for the revocation of the Liverpool Electric Lighting Orders, 1891 and 1892, and the Toxteth Park Electric Lighting Order, 1891.

LEGAL INTELLIGENCE.

MARSHALL v. SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

In the debenture holders' action of Marshall *v.* the South Staffordshire Tramways Company, Limited, Mr. Jelf, Q.C. (with him Mr. Willis Bund), on behalf of the plaintiff, on Monday appealed to the Master of the Rolls and Lords Justices Kay and Smith from an order of Mr. Justice Day in Chambers staying proceedings against the company, for whom Mr. Bramwell Davis, Q.C., appeared to resist the appeal. It transpired in the course of a long conversational explanation of the case that a receiver had been appointed in a Chancery action for and on behalf of all the debenture-holders of the company.

The Master of the Rolls: And this one debenture-holder wants to pursue a common law action on his own account?

Mr. Jelf said he would be frank, and say no doubt that was so. The fact was plaintiff wanted to accelerate the happy dispatch of the company, and to know what his fate was to be as to any possible assets.

Lord Justice Kay: But will any court allow him to bring two actions for the same thing? He has obtained a judgment as a debenture-holder in the action brought on behalf of the debenture-holders; and what more do you want or can you say you are entitled to?

Mr. Jelf: As one of the other debenture-holders, we want to prosecute our claim.

Lord Justice Kay: You being included in this very judgment?

Mr. Jelf assented, but submitted the plaintiff had a right, like any other creditor, to come in and say that his claim should be enforced without waiting for the winding-up under the other proceedings.

Lord Justice Kay: I can only say I never saw this device tried before.

Mr. Jelf assured the Court that he was innocent of having devised it.

The Master of the Rolls: Perhaps you are also innocent of having advised it.

Mr. Jelf said he would rather not go into that question, but submitted he was entitled, in some way or another, to bring the matter to a head, and was not bound under the Chancery action to wait for all the delay involved in the bringing up of accounts, but might take the ordinary course open to him in an undisputed claim, and upon it to bring about a winding-up of the company.

Lord Justice Kay: If you are right, every debenture-holder might bring a separate action, notwithstanding a judgment granted for and on behalf of all the debenture-holders.

The Master of the Rolls: Your first action you bring as and for all the debenture-holders, and ask for a receiver; and on the second you proceed also as a debenture-holder, and ask for judgment out and out for yourself. We had better hear if your junior can make out a better case than that, involving endless actions.

Mr. Willis Bund accordingly submitted that there were questions on the construction of the debenture to be tried,

Which, observed **Lord Justice Kay**, you can raise and have settled in the Chancery action quite as well as in a common-law action.

At the close of the learned counsel's submissions the **Master of the Rolls** (without calling on counsel for the company) said the sufficient answer to the application was that plaintiff had already brought an action against the company and got judgment under it, and a second action could not be brought and ought not to be allowed, and the appeal would therefore be dismissed.

Lord Justice Kay, in expressing his concurrence in that view, said that all and every question possible of being raised on the debenture could be as well settled in the Chancery Court as under a common law action, as this was. He agreed that the learned judge below was quite right in staying the action.

Lord Justice Smith assenting, the appeal was dismissed accordingly, with costs.

COMPANIES' MEETINGS.

UNITED RIVER PLATE TELEPHONE COMPANY.

The ninth annual general meeting of this Company was held on Tuesday at Winchester House, Mr. J. Irving Courtenay occupying the chair.

The Chairman, in moving the adoption of the report and accounts, congratulated the shareholders on the improved position of the Company, and that the expectations he set forth at the meeting last year had been, to a fair extent, realised, so that the directors felt justified in recommending a dividend of 3 per cent. on the ordinary share capital. The advices from the Company's representatives in the River Plate pointed, in spite of frequent fluctuations, to a distinct general improvement in business there. The collections for the year under review—£149,262—were the largest the Company had ever had for a similar period, and, taking everything into consideration, could not but be deemed to be most encouraging. The number of subscribers had increased from 5,363 to 5,798 on March 31 last, and the increase continued.

The motion was carried unanimously.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bristol.—The Committee of Visitors of the Bristol Lunatic Asylum, Fishponds, invite tenders by July 15 for supply and fixing the necessary wires, lamps, etc., for lighting the asylum by electricity.

Dortmund.—The Stadtgemeinde invite tenders by August 14 for the construction of a large electric central station. Conditions and plans may be obtained for one mark from Das Magistratsamt, Dortmund, Germany.

Hapton.—Tenders are required for the electric lighting of the village of Hapton from September 1 to April 30, 1896. Number of lights required will be about 50. Tenders to be sent to the chairman of the Hapton Parish Council before July 15.

Blackburn.—The Corporation of Blackburn invite tenders for the wiring of the town hall. Copies of the specification may be obtained from the engineer, Mr. E. M. Lacey, of 19, Old Queen-street, S.W., on payment of £1. 1s., which will be refunded on return of same accompanied by a *bonâ fide* tender. Plans may be seen at the office of the town clerk, or the engineer, from whom any further information can be obtained. Tenders must be sent in by to-morrow (13th inst.).

Wellington.—The Wellington (Salop) Urban District Council require tenders for lighting the urban area or lighting district with gas or electricity. The said district comprises about six miles of streets and roads, and is at present lighted by about 200 ordinary gas lamps and three of Sugg's patent treble lights. Further particulars may be obtained from the surveyor, Mr. G. J. Monson, C.E., 45, Walker-street, Wellington. Tenders, endorsed "Tender for Lighting," must be sent to the clerk, Urban Council, Wellington, Salop, by 12 noon on July 15.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply

Digitized by Google

of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a *bonâ fide* tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

London, W.C.—The Metropolitan Asylums Board invite tenders for the supply and running of mains in the grounds and for the wiring of buildings now in course of erection at the North-Western Fever Hospital, Haverstock Hill. Conditions of contract and specification, prepared by Prof. Ayrton, may be purchased, price 10s., at the offices of the Board, Norfolk House, Norfolk-street, Strand, W.C. Deposited plans can be seen at the hospital any weekday between 11 a.m. and 4 p.m on production of the specification. Sealed tenders prepared in accordance with the printed instructions, are to be delivered at the offices of the Board by 11 a.m. on July 18.

Datchet (Berks.).—Tenders are invited for lighting the village of Datchet, for the Barker's Bridge House Trust, during October to March, with oil, gas, or electricity. The present number of lamps is 33. Any further number hereafter to be erected in the parish to be included at the rate quoted. Tenders may be for lighting partly by one method and partly by another. The lamps must be lighted at sunset and kept alight until 1 30 a.m. The contractor must supply all requirements and fittings for the lamps (the present posts and lamps being available as far as they will serve) for the lighting as above specified, and must keep the lamps clean and in good repair to the satisfaction of the trustees. Tenders must be sent to the trustees of Barker's Bridge House Trust, care of Mr. H. L. Prior, The Priory, Datchet, by 6 p.m. on 20th inst.

Derby.—The Electric Lighting Committee of the Corporation invite tenders for the builder's work in the boiler seatings for three new boilers and in new coal-store, etc., and accessories, at the central station. Plans may be seen on application to Messrs Bramwell and Harris, engineers, 5, Great George-street, Westminster, S.W., or to the town clerk, Town Hall, Derby, from either of whom may be obtained, on deposit of £2. 2s., to be returned on receipt of a bona fide tender, a printed copy of the specification, form of tender, and bill of quantities. Tenders, on the prescribed form, must be delivered, with the specification attached and unaltered, enclosed in a sealed envelope, endorsed "Electric Lighting—Tender for Buildings," and addressed to Mr. H. F. Gadsby, town clerk, at the Town Hall, Derby, by 12 noon on 22nd inst.

Brighton.—The Brighton Town Council invite tenders for the supply and erection at their electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping; also for the supply and erection at the electricity works, North-road, of steam and feed piping, cast-iron storage tanks, feed-water filters, electrically-driven feed pumps, circulation economiser, coal-elevator, and sundries. Specifications can be obtained on application at the town clerk's office, Town Hall, Brighton, on payment of one guinea, which will be refunded on return of the specification, accompanied by a *bonâ fide* tender. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, endorsed "Tender for Condensers, etc.," or "Tender for Steam Piping, etc.," must be sent to the town clerk's office, Town Hall, Brighton, by 10 a.m. on July 15.

Valletta (Malta).—Sealed tenders will be received at the office of the Receiver-General and Director of Contracts, Valetta, or at that of the Crown Agents for the Colonies, Downing-street, London, until 11 a.m. on August 1, for the supply of materials in connection with the installation of the electric light in the civil and war department buildings in Malta. The materials are comprised under four headings—viz, (1) cables and wires, (2) tools, etc., (3) fittings, fixtures, etc., (4) sundries. Printed forms of tender and of the specifications and conditions may be obtained on application at the above office, Valletta, or at the office of the Crown Agents for the Colonies, Downing-street, London. Each tender must contain the name of the surety whom the tenderer intends to propose for securing the performance of the contract and the payment of the penalties therein established. The surety to be a person residing in the island. No notice shall be taken of any tender not accompanied by a deposit, to be made in the office of the Receiver-General and the Director of Contracts, Valletta, or in that of the Crown Agents in London, of a sum of £5 sterling, to be forfeited to the Government should the party tendering, or his surety, in the event of the tender being accepted, fail to appear for signing the contract within three days from the day of the notice given to them to that effect. If the tenderer is not resident in Malta, his tender must contain the name of an agent residing in the island, to whom, in the same tender, power must be given to represent the tenderer in the contract. Any tenders which may be delivered at the Crown Agents' office must be in sealed packets addressed to the "Director of Contracts, Malta—Tender for Materials for Electric Lighting," under cover addressed to the Crown Agents for the Colonies.

Globe Telegraph and Trust Company.—A further distribution of 3s. 5d. per share is announced on the ordinary capital, leaving about £1,200 to be carried forward.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of June the receipts were £25,200.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,969.

Durban.—The Capetown correspondent of the *Times* telegraphs that Durban is to be lighted by electricity.

Capetown and Suburban Electric Lighting Syndicate.—The payment is announced of a dividend of 7 per cent.

Stafford.—The Town Council have decided to extend the electric lighting cables along Tipping-street and as far as the new Baptist Chapel on Lichfield road.

City and South London Railway.—The returns for the week ending July 7 were £915, compared with £879 for the corresponding period of 1894, being an increase of £36

Removal.—The offices and works of the Nalder and Harrison Construction Syndicate, Limited, have been transferred to Trafalgar Works, Bow Common-lane, London, E.

Agency.—Mr. G. Straus, 130, Queen Victoria-street, E.C., informs us that he has been appointed sole agent for the United Kingdom and colonies by Messrs. Schiff, Jordan, and Co, of Vienna.

Liverpool District Lighting Company, Limited.—This Company has been registered, with a capital of £2,000, to carry on the business of an electric supply and gasworks company in all its branches.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 7th inst. amounted to £1,250, as compared with £917 in the corresponding week of last year, being an increase of £333.

Bourne Bros. and Co., Limited.—This Company has been registered, with a capital of £2,000, to adopt a certain agreement and to deal in and with indiarubber, guttapercha, and gums of every description.

Dundee.—At a meeting of the Gas Committee of the Town Council, Sir James Low and ex-Bailies Doig and M'Kinnon were appointed visitors to the gasworks and electric lighting station—ex-Bailie Doig convener.

Standard Electro-Galvanising Company, Limited. — This Company has been registered, with a capital of £4 000 in £1 shares, to carry on business as manufacturers and galvanisers of iron, steel, and other metals, or metal articles.

Bagnor (Wales)—A meeting of the City Council has taken place, at which Mr. Thomas Lewis said that the report of Mr. Medhurst, the electrical engineer appointed to assist the Council in electric lighting matters, was expected in a few days.

Chelsea Electricity Supply Company.—The directors of the Chelsea Electricity Supply Company, Limited, have declared an interim dividend on the 6 per cent. preference shares at the rate of 6 per cent. per annum for the half-year ending June 30.

Buxton.—The Urban District Council have held a meeting, at which a discussion took place as to what was being done by the Electric Lighting Committee, and Mr. Lawson expressed surprise at the scheme dying out after so much had been said about it.

Bury.—At a meeting of the Electric Lighting Committee of the Town Council it was resolved unanimously, after a report from the borough engineer, that the Council be recommended to defer the appointment of an electrical engineer until further enquiries have been made

Pinson and Evans, Limited.—This Company has been registered, with a capital of £20,000, to acquire as a going concern the business of furnishing ironmongers, ironfounders, and galvanisers, etc., as now carried on by Pinson and Evans, Wolverhampton, and to develop and extend the same.

Private Bill Legislation.—Mr. Mellor's Committee on Unopposed Bills has passed provisional orders authorising the London United Tramways to construct additional lines at Hammersmith and Acton, and empowering the Corporation of Windsor to undertake the electric lighting of Windsor and Eton.

Direct United States Cable Company.—A final dividend of 2s. per share, free of income tax is declared, payable on and after 31st inst., making, with the interim dividends already paid, 2 per cent. for the year ended June 30 last, and, after placing £7,000 to reserve fund, carrying forward a balance of £1,410.

Crosby.—The Urban District Council have held a meeting, at which communications were read from two electric lighting companies giving notice of their intention to apply in the next session of Parliament for provisional orders, giving them authority to supply the electric light within the Council's district.

Tonbridge.—The District Council have held a meeting, at which the Guildford Electricity Supply Company intimated their intention to apply to the Board of Trade for an order to supply electricity in the district, and the Council decided to deal with this as they had done a previous notice by the Holloway Company.

Sevenoaks.—The Urban District Council have received a letter from the Guildford Electric Supply Company, Limited, of Great George-street, Westminster, giving notice of their intention to apply for a provisional order to supply electricity for private and public purposes within the area of the Sevenoaks Urban District Council.

Wells.—The Town Council have held a meeting, at which a letter was read from Messrs. Davies and Roach regretting that they were unable to return the electric lighting contract signed

Digitized by Google

by Mr. Dixon Browne, and suggesting the appointment of another electrician. The letter was referred to a committee of the whole Council.

Lewisham.—The District Board have held a meeting at which the Capital and Counties Electricity Supply Company, Limited, gave notice of their intention to apply to the Board of Trade for a provisional order to electrically supply consumers in the area of the Board's jurisdiction. This communication was formally received.

New Mains.—The London County Council have sanctioned the laying of mains by the Metropolitan Electric Supply Company in Little and Great Wild streets, Kemble-street, Russell-street, Wellington-street, Exeter-street, and part of the Strand. The work is necessitated by the recent fire at the company's generating station in Sardinia-street.

Bexhill.—The Urban Council have held a meeting, at which a letter was received from the Bexhill Water and Gas Company, asking that, in the event of the company undertaking to supply the town with electric light, the Council would acquiesce in their action. On the motion of Mr. S. Smith, the letter was referred to the Highways and Lighting Company.

Eastern Extension Telegraph Company.—Notice is given that the interest on the Eastern Extension Telegraph Company's 4 per cent. mortgage debenture stock for the half-year ending July 31 inst. will be paid by warrant on August 1. The 4 per cent. mortgage debenture stock register will be closed from the 27th to the 31st inst., both days inclusive.

Snaefell Electric Railway.—The Snaefell electric railway, one of the most enterprising works ever undertaken in Manxland, is rapidly approaching completion, and will be ready for opening when the rush of visitors comes a few weeks hence The railway opens out magnificent mountain scenery, and goes to the summit of Snaefell, the highest mountain in the Isle of Man.

Bradford.—The adoption of the minutes of the Gas and Electricity Supply Committee was at the last meeting of the Town Council moved by Mr. W. C. Dixon (chairman), and seconded by Mr. J. Kay (deputy-chairman). It appeared that arrangements had been made that an entirely fresh test of the oil-gas process of Dr. Dvorkovitz should be carried out. The minutes were adopted.

Hastings.—A meeting of the Urban Council has been held at which the clerk reported that he had received a letter from the Bexhill Water and Gas Company asking whether the Council would give them their support, if in the future they were to supply the town with electric light. On the proposition of Councillor S. Smith, the letter was referred to the Highways and Lighting Committee for consideration.

Chiswick.—The District Council have held a meeting at which the clerk read a letter from Messrs. Bourne and Grant agreeing to erect a shaft at the electric works station to be used as a dust destructor, in accordance with the suggestion of the Council, in the event of the Council agreeing to pay £750 towards the cost of the shaft and supply the steam for the use of the destructor. The matter was referred to a sub-committee

Ambleside.—A meeting of the District Council has been held, at which a letter was read from Mr. Moore with reference to the electric light. Colonel Rhodes was of opinion that the Council should oppose any outside movement on the sole ground that as soon as the Council had obtained the gas and water works it might then think it worth while to have its own electric works. Mr. Hunter seconded this, and it was referred to the Council.

Appointment Vacant.—The Birmingham Corporation require the services of an engineer fully competent to take entire charge of the electric light and power installation in the new school, Suffolk-street. Salary £2. 10s. per week. Applications, stating age, qualifications, and past experience, and accompanied by copies of not more than three recent testimonials, must be sent to Mr. Geo. Mellor, secretary, offices of the school, Paradise-street, Birmingham, on or before 13th inst.

Aberystwith.—The Town Council have held a meeting, at which the Public Lights Committee presented their report, which recommended that the surveyor should be instructed to have the lamps removed from the pillars on the Marine-parade, that an additional lamp should be placed on the Penparke-road, and that the report of Mr. A. H. Preece in regard to the electric lighting of the town should be adopted. After discussion, it was decided that the two recommendations in question should be referred back to the Public Lights Committee.

Ilfracombe.—A letter has been received from the electric light and power company by the Urban District Council stating their intention to apply for a provisional order to supply the town. Messrs. Baker and Co., parliamentary agents, wrote to advise the Council to apply for an order themselves At the meeting of the Council Mr. Walters said it would be wise for that body to apply, as the gas should be supplemented by electricity. It was decided that the whole question of lighting should be considered at a special meeting of the Council.

Cheltenham.—A meeting of the Town Council has been held, at which Alderman Norman brought up the minutes of the Electric Lighting Committee. He pointed out that the outlay was only between £800 and £900 in excess of the estimate, and that the difference, about 5 per cent., was very small as compared with the experience of some other towns. In addition, many things not originally contemplated were included in the expenditure. The machinery in use was working in the most satisfactory manner. Mr. Margrett thought the overseers had acted very fairly in assessing the undertaking at £400.

Eastbourne.—At the last meeting of the Town Council the minutes of the Lighting and General Purposes Committee stated that the town clerk reported that he had requested the Eastbourne Electric Light Company to make a reduction from their accounts with respect to electric lighting, and a letter was read from the secretary stating that his company were willing, as from the 30th inst., to make a reduction of 1d. per Board of Trade unit in the lighting supplied to the Town Hall and bandstand. It was resolved that the best thanks of the committee should be tendered to the company for such reduction. The minutes were confirmed.

Blackpool.—The Town Council have held a meeting, at which the report of the Electric Lighting and Tramways Committee showed that it had been resolved that a sub-committee, consisting of the Mayor, the chairman (Councillor Pearson), Alderman Buckley, and Councillors Heap and Smith, should be desired to consider Mr. Hammond's report of June 17 on the present position of the Corporation's electricity works and submit recommendations to the committee thereon, and that until a further extension of the Corporation's electricity works was made the committee felt unable to accede to new applications for supply of electrical energy.

Liverpool.—The Special Lighting Committee of the Liverpool Corporation have adopted a resolution that the Council be recommended to consider, and, if thought expedient, to approve of the intention to make application to the Board of Trade by the Mayor, aldermen, and citizens of the city of Liverpool, acting by the said Council of the said city, and being the local authority of the said city, for the purposes of the Electric Lighting Acts, 1882 and 1888, for a provisional order to supply electricity for public and private purposes, under the provisions of the said Acts, within the area of the city of Liverpool, as the same may exist at the time of granting the said order.

Capetown.—An interview between the representative of a weekly newspaper and an ex-mayor and well-known merchant of Capetown throws a new and not altogether satisfactory light upon the policy of requiring that the origin of all imported manufactures shall be declared. It would appear that German and American manufactures are supplanting our own productions in the markets of South Africa. This is said to be specially noticeable in hardwares, it being stated that Cape Colony storekeepers are importing enormous quantities of German goods, and that even the electric lighting machinery for Capetown was made in Germany and erected by German workmen.

National Telephone Company.—The directors of the National Telephone Company, Limited, have resolved, subject to final audit, to recommend a dividend for the half-year ending June 30 at the rate of 6 per cent. per annum, less income tax, on the amounts paid up on the first and second preference shares; at the rate of 5 per cent., less tax, on the amounts paid up on the third preference shares; and at the rate of 5 per cent., free of tax, on the amounts paid up on the ordinary shares. The sum of £35,000 is carried to reserve, and about £3,000 goes forward. The transfer books in respect of the preference and ordinary shares will be closed from 13th to 26th inst., both days inclusive.

Hampstead.—The Vestry have held a meeting, at which the Lighting Committee recommended that an electric lighting main for supply to consumers be laid down from the West End-lane extension along Inglewood-road to the corner of Holmdale-road, at an estimated cost of £86; that three smaller high-pressure feeders be substituted for the one large feeder ordered for the High-road, Kilburn, extension, at an additional cost of £271; that two smaller high-pressure feeders be substituted for the one large feeder ordered for the West End-lane extension, at an additional cost of £76; and that the necessary alterations be made in the panels of the switchboard at the central station, at an estimated cost of £15. The report was adopted.

Acton.—It was reported at the last meeting of the District Council that a letter had been received from the secretary of the Capital and Counties Electricity Supply Company, stating that it was intended to make application on or before December 21 next, by memorial to the Board of Trade, in pursuance of the Electric Lighting Acts 1882-1888, for a provisional order, to be confirmed in the ensuing session of Parliament, authorising the said Capital and Counties Electricity Supply Company to supply electricity for public and private purposes within the area of the jurisdiction of the Urban District Council of Acton. A letter had also been received from Messrs. Limbrey and Co., the solicitors to the company, to the same effect. It was remarked that at the proper time the Council would be prepared to oppose the grant of the provisional order, and Mr. Eydmann added that if the company got the order it would not be of much use to them.

Electricity in Mines.—At the annual general meeting of the Pigg's Peak Development Company, Limited, Mr. G. T. Rait, the chairman of the company, said that though they had the utmost confidence in Mr. Dicey as manager, they felt that in matters relating to the laying out and development of the property, such as the question of the use of electrical power for the working of the mill, they ought to have the best possible advice, and they had therefore appointed Mr. Knobel, who was well known on the Rand, as consulting engineer to advise with the manager as to the laying out of the mine. Mr. Knobel, after going over the property, had already made a report, and with regard to the fitting up of the electrical power the company would be guided in a large measure by what he said. The policy of the directors certainly was to work the Pigg's Peak property. They had had several assays of the ore made, and the average result showed 19dwt. and some odd grains to the ton. On the economical treatment of that ore, therefore, it all depended whether a profit could or could not be

Digitized by Google

made. They must get the contract for the supply of electrical power on as advantageous terms as possible.

Douglas Electric Tramway—The arbitration proceedings of the Douglas and Laxey Electric Tramway Company took place at Douglas on Thursday last week before Messrs. Jas. Cowell, Corlett, and Robert Cain, arbitrators appointed by the Lieutenant-Governor to decide in any disputes arising in the acquirement by the company of land for the completion of their tramway. The question at issue was the price to be paid by the company to Mr. Hall, landlord of the Commercial Hotel, Laxey, for 725 yards of land opposite to his hotel, required by the company for their terminus at Laxey. Mr. T. Kneen appeared for Mr. Hall, and Mr. C. B. Nelson and F. Browne for the company. The land had been estimated by Mr. T. Wainwright, valuer, Liverpool, and others, on behalf of Mr. Hall, to be worth £2 a square yard, free of restriction; whilst others, on behalf of the company, said the value of the land, free of restriction, was not more than 15s. a square yard. A compromise was come to, by the terms of which the electric tramway company agreed to pay Mr. Hall £250 for the land, pay all costs of both sides, and restrict themselves not to erect any refreshment-room or hotel on the land in question.

Brighton.—The Town Council have received a communication from the Local Government Board with their sanction to the Council borrowing the sum of £43,650 for the purposes of electric lighting, and £2,500 for the purposes of public lighting, and the Council have referred the letter to the Finance Committee, with power to take the necessary steps to obtain the money. At their meeting on June 17, the Lighting Committee approved the action of the town clerk in requesting the gas company to continue the lighting of Marine-parade, etc., until September 30 next, the notice given to discontinue such lighting expiring on June 24, and the Corporation not being yet ready to light these streets with electricity. The committee again considered the letter from Councillor Halliwell, with reference to the lighting of Lewes-road, and suggesting that some of the Sugg's lanterns now in use on the Marine-parade should be removed there. It was resolved that the lanterns in Lewes-road be fitted with burners to consume 6ft. of gas per hour each, instead of 5ft. as at present. On the motion of Councillor Stafford, the proceedings of this committee were agreed to at the last meeting of the Town Council.

Sheffield.—A meeting of the Town Council has been held, at which Mr. Duncan Gilmour said that he noticed that the electric light company had laid their mains along Fulwood-road from Broomhill to Ranmore, and had disturbed the asphalte on the south side of the road to a width of about 14in. He also noticed that the whole length of the asphalte causeway about 6ft. wide on the south side had been, or was in course of being, removed and renewed. He wanted to know who was paying for this, what proportion were the ratepayers paying, and what would be the cost of the whole work chargeable to the ratepayers? The Mayor replied to the first question, the electric light company; to the second, "nothing;" and to the third, according to what other work might be done in connection with the paths. In moving the minutes of the Highway and Sewerage Committee later, the Mayor remarked that he might inform Mr. Gilmour that there was an arrangement by which the electric light company paid a certain amount of the cost of the footpath which he had mentioned. This amount covered the whole of the cost of asphalting, but not any extra cost incurred in the matter of kerbstones which the committee might consider prudent to have done.

Sale.—The Urban District Council have held a meeting, at which a letter was read from the secretary of the Altrincham Electric Supply Company, dated June 28, saying he was requested by his directors to notify that it was their intention to apply to the Board of Trade for a provisional order to supply electricity to the district, and asking for the sanction of the Council. Considerable discussion ensued as to allowing any outside authority to come in to supply electricity, and ultimately the matter was referred to the Parliamentary Committee. The Secretary also wished to know if the committee would allow him to appear before them to be heard, and to tender advice at any meeting that might be held. To this Mr. Wainwright said it might be a waste of the gentleman's time to be present, as the committee might wish to adopt the principle to supply electricity themselves to the township. Mr. Lloyd thought if the secretary was heard he might say something they could go upon, and so get ideas they might work out. Mr. Wells said he would be very chary indeed in granting powers to any company at the present time and so tie their hands. Mr. Critchley did not understand that the committee would have any power to grant anything.

Kingswood (Bristol).—The District Council have held a meeting at which a letter was read from Mr. E. Caspar, who had had an interview with the chairman and the clerk respecting Parfitt's patent and extra lighting. The document suggested that the Council should purchase the plant, and the conditions of extensions mentioned were: the additional power for public and private lighting would be that, beyond the power required for lighting, there should be power supplied for sale to small and large manufacturers. The letter further asked for particulars of the proposed extension of lighting. The Chairman said he could not admit that Mr. Caspar had been told by him that the Council entertained the purchase of the system. Mr. Wilshire said that they had not yet had the light that they had previously arranged for. Mr. Bridges was of opinion that their authority was to call upon the firm to supply the light they needed without entertaining the purchase of the system. The Chairman mentioned that if they ever did entertain the purchase of the light, he should certainly advocate the wires being put underground. They were not quite satisfied with the way in which their streets were lighted at present. It seemed to him that their best plan was to go in for additional lighting without thinking of purchasing the installation. It was then resolved that a list of the extra area to be lighted should be got out and forwarded to Mr. Caspar.

Dover.—The Town Council have held a meeting, at which the minutes of the committee appointed to consider the question of the quantity of light to be supplied in the Connaught Hall reported and recommended a certain number of lights which should be turned on and no extra charge made to the hiring of the hall. The cost would be 5s. 6d per hour. If the full number of lamps was required, a charge of 5s an hour should be made. Alderman Pepper carefully explained the report, and stated that about half the lights would be used. The additional cost over gas would be 3s. an hour. Councillor Ayres moved that the report be adopted. Councillor Burkett seconded. Alderman Peake said that Alderman Pepper had informed him that the extra cost over gas would be 5s., and taking that as correct would make the average cost per night 15s. Alderman Peake said that he did not think the ratepayers would approve of £112 being thrown away to the electric light company. Alderman Pepper said that if a gentleman got up and first made a statement which was incorrect, and then did a rule-of-three sum on an incorrect basis, there was no wonder he would get something startling. There were 134 lamps at ½d. each per hour, which was 5s., or 3s. 1d. extra. Alderman Peake: Then it is £70 a year more. The recommendation of the committee was carried. It was decided to make a connection with the mains at a cost of £7. 3s.

Tunbridge Wells.—Councillor Ryder asked at the last meeting of the Town Council when the electric light would be turned on. The Mayor explained there had been a delay with the machinery, some of which had to go back. Councillor Putland asked what was the salary of the electrical engineer, and why he had to give a guarantee. Councillor Burton said that but for the delay the arc lamps would have been lighted a week before the Council meeting. The Town Clerk pointed out that all officers had to give guarantees; the salary was £250. Alderman Delves asked the probable revenue from the expenditure of £12,000 on extending the mains. Councillor Wilmott asked if there would be no public demonstration to open the electric lighting. Councillor Wood said the committee felt that any public opening should take place in the Town Hall, and the light was now being installed there. They hoped to arrange some ceremony by September, but meanwhile the light in the streets would be turned on soon as possible. In reply to Mr. Delves he would not be drawn into prophecy, but from the number of applications for the light coming in he looked for a good return. It was decided to appoint Mr. H P. Boot, of Dublin, as electrical engineer. The town clerk was instructed to communicate with Messrs. Kelsey as to one of their tenants lighting his premises by electricity, and the engineer to make arrangements for the lighting of the arc lamps in the streets as soon as possible.

Monmouth.—Pursuant to a request by the Corporation to borrow £19,000 for the purpose of carrying out a combined scheme for sewage and its disposal, and the installation of electric light for public and private use in the borough, Colonel W. M. Ducat, R.E, Local Government Board inspector, has held a public enquiry. Mr. Ram represented the Corporation. The machinery for generating electric energy and pumping sewage will be fixed on the River Monnow, water being the motive power, and a stand-by steam engine to be kept for use in case of floods. The only opposition was a petition, signed by about 100 ratepayers, praying that the loan be not granted for electric lighting. The objectors were represented by Mr. Corner, Hereford. The engineers are Messrs Bramwell and Harris, and C. N. Lailey, London. In the course of the enquiry, which lasted about five hours, it was shown that by lighting the public lamps by electricity a considerable saving to the rates would be effected, and this, added to the probable sale of electric light for private use, would bring the cost of repayment of the loan from 1s. 2d. in the pound down to 6¼d. in the pound. No witnesses were called in support of the petition, and Mr. Ram commented on the number of names of directors and shareholders in the gas company appearing therein. At the conclusion of the enquiry, Mr. Ram asked the inspector to recommend the longest time possible for repayment of the loan.

Worcester.—The Town Council have held a meeting, at which the Deputy-Mayor moved the adoption of a reduced scale of charges for supply of current, for motive power, and for the hire of motors. Mr. Williamson said that in order to make the water power pay it was necessary to get a day load, a night load being already assured. They wanted to see the water power used during the daytime, and every horse-power they could get employed meant so much profit. Many people who used little power would find it more economical to use the current than to lay down a gas or steam engine, and if they could get 100 h.p. per day employed, that would pay the whole of the interest on the capital. It ought not to be difficult to get 100 h.p. taken up, and they might do a great deal in a year or two. Mr. Chaplin seconded. The Sheriff remarked that the electricity business seemed to be a constant source of surprises. Had they already reached the limit of the water power and of night consumption? Mr. Williamson replied in the negative, saying that although they had 12,000 lamps on, as was originally contemplated, they were not all burning. The Sheriff asked if it was the fact that the power was not sufficient for the waterworks pump and the lamps to be used together. Mr. W. Caldicott explained that the electricity was employed at the waterworks when it was not required for other purposes. Alderman Higgs supported the resolution,

Digitized by Google

hoping that the power would be taken up, so that the scheme would result in profit rather than continue a burden on the ratepayers. Alderman Day advocated it as an auxiliary to their income. The resolution was carried.

Llanelly.—The surveyor's report upon tenders for electric lighting having been read at a meeting of the Borough Council, instructions were given to call a meeting of the Estate Committee to consider the same. The clerk read the following letter received from the London solicitors of Messrs. J. C. Howell, Limited, Llanelly: "To the Urban District Council of Llanelly.—On behalf of Messrs. J. C. Howell, Limited, of 24, Queen Victoria-street, in the city of London, and of Llanelly, in the county of Carmarthen, electric lighting contractors, we beg to give notice that it is their intention to apply during the parliamentary session of 1895-6 for a provisional order, under the Electric Lighting Acts 1882 and 1888, granting to the applicants statutory powers under the said Acts within the said urban district of Llanelly." The Chairman suggested that the matter be referred to the Property and Estate Committee Replying to questions, the Clerk said it was necessary that such a notice should be given to the Council, in order that they might lodge any protest against the order being granted if that course was found advisable. It was not certain as to what they would decide with regard to their own order for electrically lighting the town. Mr. D. W. Rees, in reporting to the Council, said that the committee had not gone fully into the question, but hoped to be able to present a report at the next meeting of the Council. The letter was then referred to the committee for further consideration. It was also reported that the question of placing the new town hall in telephonic communication with the old market stores was under consideration, and the architect was instructed to obtain further tenders for the same.

Derry.—A meeting of the Lighting Committee of the Corporation has been held, at which the Mayor presided, and there were also present Alderman Johnston, Councillors Hastings, Thompson, M'Kane, Brown, Boal, M'Cully, and Turner. Mr. Stafford read the minutes of last meeting. Councillor Hastings protested against the resolution proposed by Alderman Pollock, and seconded by Councillor Donnell, "that Mr. Christie be directed to give an estimate of the cost of the private lighting of the city by electricity." This had been carried in his absence, and he protested against it. If the Corporation and Alderman Pollock and Councillor Donnell thought he was not competent to be the chairman of the Lighting Committee, let them move that he be dismissed He challenged the man who wrote the resolution behind his back to justify it He moved that the resolution be expunged from the minutes He believed the committee passed it goaded on by Mr. Pollock and Mr. Donnell and he would not stand it. The Mayor said the matter could be brought up at the Council meeting. Councillor Hastings went into the matter of the accounts with Messrs. Siemens Bros., and said he was not satisfied with them, and would like time to consider them. Mr. Algeo entered into an explanation of the items, which seemed to satisfy Councillor Hastings. Councillor Thompson put some questions to Mr. Algeo on the electric lighting account. Mr. Algeo said the Corporation would be about £1,600 short. Councillor Hastings, referring to an item in the account with Messrs. Siemens Bros. about the use of gas, said he thought the Corporation should not press the matter about the gas. Mr. Algeo said that Messrs. Siemens Bros. had given the Corporation the cost of opening the roads and streets.

Cork.—Notices of their intention to apply for a provisional order to supply electricity within the city of Cork were read at the last meeting of the Corporation from Messrs. Hanrahan and Co., solicitors, on behalf of the Cork Gas Consumers' Company; Mr. R. A. Atkins, on behalf of the Cork Electric Light and Power Company, Limited; and from Mr. Edward Felton, on behalf of the Electricity Supply Company of Ireland, Limited. Alderman Julian enquired if they could do anything there. The Town Clerk said the matter should be referred to a committee and a special meeting held. Alderman Julian then proposed that a special meeting be convened for the purpose of considering the applications that had been made. The Town Clerk pointed out that there was an Electric Lighting Committee in existence. Mr. Dwyer asked if there were any of its members yet alive. The Mayor said he was one of them Mr. Barrett said he was another. He would oppose the gas company and he would oppose the new company also. He had the greatest respect for them all but he had more respect for the citizens of Cork, whose property was in question. Sir John Scott said he was one of the promoters of the new company, and he could assure them that the company would take every reasonable precaution to preserve the interests of the citizens After some further discussion, the matter was referred to the Electric Lighting Committee, composed of the following 14 members of the Corporation, who were connected with neither the new electric lighting company nor the gas company: the Mayor; Aldermen Crean, Creedon, Hungerford, Walsh, and Sheehan; Councillors Barry, Cronin, O'Donnell, Lucey, Farrington, Bogan, Franklin, and Kinmonth, with a request to report on the question of lighting the city by electricity generally.

Weybridge.—The Urban District Council have held a meeting, at which the Highway and Lighting Committee recommended that the contract for the public lighting should be allowed to run out. They further suggested that the clerk write to the Weybridge Electric Lighting Company stating that the Council would not require them to submit a contract for lighting. Mr. Bilney thought no definite steps should be taken until a meeting of the ratepayers had been held. There was now little more than two months before the present contract would expire, and he considered the Council was adopting the eminently dangerous policy of drifting. The question of public lighting was one which it was eminently fitting should be discussed by the ratepayers. He moved that no definite steps should be taken by the Council as to the future lighting of the village, until a public meeting shall have been held. Dr. Powell seconded. Mr. Ward thought the Council should be put into a position of knowing the exact value of the stock before they went before the ratepayers. The Chairman agreed, but remarked that he thought the resolution was a little premature. They had no idea in their heads as to what they were going to do. Mr. Bilney said he wanted the full facts placed before the Council before the public meeting was held. Mr. Reed said many of the ratepayers were anxious for a public meeting to be held on the question. Mr. Bilney thought the Council should have expert opinion on the matter. Mr. Chambers moved, as an amendment, that if the Highway Committee, after consideration, thought it desirable, a public meeting should be called to consider the future lighting of Weybridge. Mr. Rowland seconded, and the amendment, on being put, was carried. It was also resolved to appoint a small committee, and to employ an engineer, as suggested by Mr. Bilney. The committee consisted of Messrs. Chambers, Ward, Bilney, Jarvis, and Dr. Powell.

Amazon Telegraph Company, Limited.—This Company has been constituted, with a capital of £250,000 in £10 shares, to connect by cable the city of Manors, capital of Amazonas State and chief emporium of the Brazilian rubber trade with Para, the capital of Para State at the mouth of the Amazon. There will be, according to the prospectus, intermediate stations or branch lines at various places in the two states, and at Para the cable will join the land lines of the Brazilian Government, and the Western and Brazilian Telegraph Company's cables, connecting with the rest of Brazil and the Argentine Republic, will be placed in communication with Europe and the telegraph system generally by the cables of the Brazilian Submarine Telegraph Company. A concession has been granted by the Brazilian Federal Government including the following privileges: exclusive cable rights in the River Amazon for 30 years in the zone comprised between Para and Amazonas States; an annual subsidy in gold during the first 20 years of concession of £17,125; all favours granted to similar Brazilian enterprises and permission to enter into agreements with the Para and Amazonas Governments to establish other branch cables. The system will revert to the Federal Government at the end of 30 years, and the Government have also power to purchase after 10 years at a price based on the value of the works and the profits of the previous five years. The cables, which are to be about 1,365 miles in extent, are to be laid by March, 1896. Figures are given of the trade of the Amazon Valley and Para, and statistics of the telegraphic traffic, and the proportion due to the trade of the Amazonas and Para States, should be, it is estimated, 3,000,000 words. But calculating on telegraphic traffic to the amount of the traffic of 1894 of the city of Para alone the directors anticipate a gross revenue, together with subsidy, of £53,375, sufficient, after providing for working expenses, amortisation fund to redeem capital, and reserve, to pay over 10 per cent. on the capital. A large increase on these figures is, however, expected. The list closed on Wednesday.

Kingstown (Dublin).—A special meeting of the Kingstown Town Commissioners has been held, at which Mr. A. S. Findlater, presided. Mr. Clifton Robinson, C.E., and Mr. R. K. Clay, solicitor, were present. The meeting was held for the purpose of consulting with Mr. Robinson in reference to matters in dispute between the Kingstown Commissioners and the electrical tramway company in reference to the proposed double line through George's-street. Mr. Robinson (by permission of the meeting) made a statement, setting forth the views of his company on the merits of a double and single tram line in crowded places. He referred to the conditions under which it had been arranged with the Commissioners that a double line should be laid through George's-street, which conditions had not been imposed on them by the other townships. He pointed out that under the agreement to lay a double line, the tramway company would have to pave the entire street, but the company felt that it would be the only way to satisfactorily work the system. He pointed out that the narrower and the more congested the traffic might be, the more reason there would be for a double line. They proposed laying some cross-over lines which would obviate obstructions. If a single line was laid the Commissioners would find that they would never be free from obstructions, and then they would not be in a position to rectify their mistake. The company had entered into contracts for the double line, and time was also a great consideration with them just now. The rolling-stock was ready for delivery, and it would equal anything of the kind in the world. The cars would cost £800 each. Mr. Clay having been heard, Mr. Atwool moved a resolution approving of the double line, and calling on the company to proceed with the work in accordance with their parliamentary powers. Mr. Wallace seconded the motion. Mr. T. W. Robinson moved, and Mr. Moran seconded, an amendment to the effect that the line should be single from St. Michael's Hospital to Clarendon Park, West. The amendment was lost by 11 votes to 6. The original motion was adopted by the same division.

Barnet.—A meeting of the Urban District Council has been held, at which the clerk reported that he had attended at the Board of Trade office with reference to the provisional order for electric lighting. He was informed that the order would be further extended provided the Council satisfied the Board that they were doing something in the matter. Mr. Baughen asked if the order ran for another 12 months. The clerk replied that it did, Father Bampfield proposed that a special committee should

Digitized by Google

be appointed, consisting of not more than four members, to go into the question of lighting and the water supply, and to report to the Council once a quarter. He spoke of the great importance of the question of lighting the district with the electric light, and suggested that the special committee in reporting from time to time should inform the Council of those towns where the electric light had been placed and had proved a success, and those towns where it had been placed and proved a failure. He was in favour of the appointment of a committee of four, because he did not believe in large committees. Mr. Rogers seconded the motion. He said he felt that the General Purposes Committee could not give the necessary time to these particular subjects. Mr. James expressed himself surprised at the motion. He said that Father Bampfield knew what the General Purposes Committee had done at their recent meetings with regard to the subject of electric lighting. If they started cutting down the number of a committee they might as well cut down the lot. He saw no reason for making such a reduction in the numbers. Mr. Baughen said he could hardly go with the mover of the proposition. Large committees had always been appointed in order that a quorum might be the more easily ensured. Mr. Parsloe observed that he was amused at some of the arguments in favour of the proposition. It would seem that there was some fear that they were going to rush the electric light. Personally he was not at all inclined to do so. He saw no necessity for the appointment of this committee. Father Bampfield replied on the discussion, and pointed out that the General Purposes Committee already constituted the majority of the Council, and that therefore it really constituted the governing body of the town. He thought the Council had not exactly taken hold of what he intended in the proposition. It was rather a surprise to him to hear complaints of the amount of time required of the members They must be prepared to give up their time. He had suggested that a committee of four should consider the matter of electric lighting, more especially since the matter required a good deal of reading and study. It would, indeed, be unfortunate, he thought, if they could not obtain four men who would undertake the study of this matter. He felt compelled to renew his proposition, which he hoped would be carried. The chairman reminded Father Bampfield that the General Purposes Committee could appoint a sub-committee to consider any particular matter. On being put to the vote four members voted for the resolution and five against it.

Birkenhead.—At the monthly meeting of the Town Council Alderman Deakin moved the proceedings of the Finance Committee, and referred to the acceptance of the tender by Messrs. Holme and Green, Liverpool, for the erection of the central electrical generating station in Bentinck-street for £4,440. Mr. Shoolbred, the engineer, had recommended tenders—which had been accepted—for the engines, dynamos, etc., to be delivered at certain times, and it was necessary to have a building ready to house them when delivered. The tender of Messrs. Holme and Green was considerably below the others, and the work was to be finished in six months However, some mistake had arisen owing to one of the sub-contractors having omitted a whole set of items amounting to £378. A special meeting of the committee was called, and it was seen that the mistake was a *bonâ fide* one, and that even with the addition the tender was still £80 below the others. Mr. Snape moved that the recommendation to alter the tender should be referred back. Alderman Walker seconded, and suggested an adjournment for a week Alderman Bloor protested against the Council voting on the sum of £4,440, and then it being taken as referring to £4,818. It was most irregular, and the latter sum was really not before the Council. Mr. Byrne thought the contract should be given to Mr. J. Shaw, a Birkenhead contractor, as his amount was only £82 higher. Alderman Deakin said the committee had taken the utmost precautions that there should be no knowledge of what the other tenders were. It was a *bonâ fide* mistake, and the committee thought it desirable to amend the tender. After further discussion, the amendment was carried by 20 votes to 16 At Wednesday's meeting of the Town Council Mr. Gostenhofer moved the confirmation of the proceedings of the Finance Committee, which included a resolution recommending the acceptance of a tender of Mr. John Shaw, of Birkenhead, to erect the buildings in connection with the central electrical generating station in Bentinck-street for the sum of £4,900. Mr. Gostenhofer said it would be remembered that at the last meeting of the Council the Council declined to confirm the tender of Messrs. Holme and Green, of Liverpool, who had asked leave to amend their tender. The Finance Committee again went through the tenders, and now submitted for acceptance the tender of Mr. John Shaw. Alderman Walker seconded. The town clerk (Mr. A. Gill) read a letter from Messrs. Holme and Green, in which those gentlemen said they considered the action of the committee showed a great want of consideration for them. At the committee meeting they were informed that the revised tender was accepted, and they immediately made arrangements for and practically commenced the work. Further, in accordance with the request of the committee, they exposed their estimates and private correspondence to the architect, and they could hardly understand the justice of a summary notice informing them that another tender and a higher one than theirs had been accepted. There was no comment on the letter, and the proceedings of the committee were confirmed.

Wolverhampton.—At the meeting of the Wolverhampton Town Council on Monday last, the Lighting Committee presented the following report with respect to a proposal for the extension of the electric lighting plant: "At a meeting of the Council, held on December 11, 1893, your committee were authorised to apply to the Local Government Board for their sanction to a loan of £30,000 for the purpose of establishing an electric light undertaking under the Wolverhampton Electric Lighting Order, 1890. The sanction to the loan was obtained on February 15, 1894. With the moneys placed at the disposal of your committee the installation has been completed. Since the opening of the works on January 30, 1895, by Lord Kelvin, a continuous supply of electrical energy for public and private purposes has been supplied within the borough. Your committee are pleased to report that the applications for electric light for private purposes have been very numerous, and the consumption consequent upon these demands, in conjunction with the energy required for street-lighting and for the lighting of the municipal buildings, has at the present time nearly reached the total capacity of the existing plant. Your committee anticipate further customers during the coming winter. To enable them to supply the energy required, your committee deem an extension of the plant necessary to the extent hereafter appearing. The success which has attended the lighting of the streets by electricity encourages your committee to erect nine additional arc lamps. These will be placed in Horsley-fields, Snow-hill, Worcester-street, and Chapel-ash. The capacity of the present works, including spare plant, is 8,000 8-c p. lamps. The lamps at present attached to the system, including the nine additional arc lamps, amount to 7,236 8-c p. lamps, leaving a balance of 764 8-c.p. lamps. This narrow margin is insufficient to meet the probable requirements of the coming winter. Your committee, therefore, recommend that the plant be increased in capacity to the extent of 3,300 8 c p. lamps. Tenders have been obtained for the works and machinery in respect of this additional plant, and as it became necessary in order to ensure delivery thereof in time to meet the increased demand, your committee have, subject to the approval of the Council and to the Local Government Board, accepted the following: Messrs. Thomas Parker, Limited, for the supply of electrical machinery, £2 232; Messrs. Marshall and Son, for the supply of an engine, £845; Messrs. H. Willcock and Co., foundations, trenches, etc., £94; Messrs. Callender, Limited, for extension of arc mains and distributing mains, £536; various contractors, for arc lamps, posts, carriers, etc., £268; for steam-pipes, floor-plates, sub-station meters, cables, etc., £250; making a total of £4,225; add for extension of mains necessary as fresh applications for electric light are received, £775; which makes a total of £5,000. Your committee, therefore, beg to recommend (1) that the action of the Lighting Committee, in accepting the tenders of Messrs. Thomas Parker, Limited, Messrs. Marshall and Sons, Messrs. H Willcock and Co., Messrs. Callender, Limited, and other contractors for the works previously enumerated, be approved and adopted; (2) that application be made to the Local Government Board for their sanction to a loan of £5,000 for the purposes previously set forth, and that as and when such sanction has been obtained the Finance Committee be authorised to raise all necessary moneys, either by the issue of Wolverhampton Corporation Stock, or otherwise, as they may deem advisable." On the motion of Mr. Johnson, seconded by Mr. Hollingsworth, the report of the Lighting Committee with regard to the proposed extension of electric lighting of the streets was adopted.

The Victoria-embankment.—The following report of the Highways Committee of the London County Council was submitted on Tuesday; but as the recommendation involves an expenditure on capital account of a sum exceeding £5 000, the consideration of it, in accordance with the standing order of the Council, had to be adjourned for a week: "On July 31 last year we submitted to the Council a scheme for the electric lighting of the Victoria embankment and gardens, and Westminster and Waterloo bridges, for which purpose the Council obtained powers in its General Powers Act of 1893, and £15,000 was provided in the Money Act of that year. The scheme which we then proposed would have involved a capital expenditure of £20,000, being £5 000 over the amount provided for the purpose, and an annual expenditure for maintenance, and for interest and redemption of loan, of £3,880. The Council, upon consideration of the recommendation, resolved that, having regard to the late period of the year, and to the fact that it would be impossible for the electric lighting to come into full operation by the ensuing winter, the further consideration of the question should be adjourned until the spring of this year. We gathered from the discussion on July 31 that one of the reasons which caused the Council to postpone the consideration of the matter was the increase of the estimate by £5,000; and we have accordingly reconsidered the scheme with a view of reducing not only the expenditure on capital account, but also the cost of maintenance. In connection with this revision it has occurred to us that, having regard to the fact that the embankment gardens, which are not open to the public at night, require to be lighted only a very short time each evening for about three months in the year, the Council would scarcely be willing to incur the expense of lighting them by electricity, especially as they are not now lighted at all. We have therefore in the new scheme which we have prepared not made any provision for lighting the gardens, and we think the Council will concur in this. In the revised scheme which we now propose duplicate plant is provided for, either set of plant being capable of lighting the embankment and the bridges; the generating station is of fireproof construction, so securing the maximum of safety; while the cost of the buildings has been reduced by omitting some of the more expensive items of ornamentation proposed in the original scheme, but the buildings will be quite as efficient. The electric lamp standards would be placed on the kerb of each of the footways, leaving the parapet lamps to be lighted, when required, by gas as at present, and the existing lamp standards on the two

Digitized by Google

bridges would be fitted with the electric light. It is proposed to provide 83 lamps in all. We would, however, point out that the light on the embankment would necessarily be to some extent obscured by the trees at the sides of the footways, and we do not see our way to obviate this. Should the Council decide to adopt the scheme, we propose to ask the Technical Education Board to allow its inspectors of art schools and classes to assist us by preparing designs for the lamp standards; and we hope to be able to obtain a design for a standard and lamp which will be worthy of being placed in this, the finest thoroughfare in London. The capital cost of the scheme is estimated at £16,590, made up of the following items: buildings £4,600, boilers and machinery £5,200, mains £2 250, lamps and standards £4,240, salaries £300, of which about £3,000 is included in respect of the two bridges. The estimated annual cost of maintenance is £2,768, in which is included—wages £700, coal £375, other stores and carbons £325, repairs £613, loan (interest and repayment) £672, rates and taxes £83. In making these estimates it has been assumed that the repayment of the loan would be spread over 42 years, which is the period for which the Council is now granting loans to vestries for electric lighting purposes. We recommend that, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, the Highways Committee be authorised to take all the necessary measures for establishing at a cost not exceeding £16,590 electric lighting for the Victoria-embankment and the Waterloo and Westminster bridges (but exclusive of the embankment gardens) authorised by the Council's (General Powers) Act, 1893; and that for this purpose the committee be authorised to obtain tenders and to enter into contracts on behalf of the Council. Mr. Thornton gave notice of the following amendment: "That the Highways Committee be instructed to obtain reports from the engineer and the chemist upon the question whetner the lighting of the Victoria-embankment and the bridges could be improved by the substitution of incandescent burners for those at present in use."

PROVISIONAL PATENTS, 1895.

JULY 1.

12651. **Improvements in electrolytical apparatus.** Richard Heathfield and William Stepney Rawson, 1, Leadenhall-street, London.

12683. **Improvements in or relating to telephone transmitters.** Theodore Berdell, 18, Buckingham-street, Strand, London.

12690. **Improved means for regulating the speed of electrically-propelled vehicles.** Camille Brault and Charles Jeantaud, 47, Lincoln's-inn-fields, London.

12697. **An automatic electric fire alarum and indicator of heavy air in a room or other enclosed space.** August Hansen and Hans Hansen Frimand, 77, Chancery-lane, London.

JULY 2.

12711. **Improvements in or connected with the insulation of copper conductors for electric light wires, cables, telephones, all electrical work, and other purposes.** Joseph Augustus London and Harry Percy Bailey, 29, Eldon-street, Newcastle-on-Tyne.

12719. **An improved filament for incandescent electric lamps.** Joachim Estrade, 70, Wellington-street, Glasgow.

12772. **Improvements in automatic safety devices for electric circuits.** Lewis G. Rowand, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 3.

12824. **Improvements in or relating to engines for ventilating-fans, dynamos, steam launches, and other purposes where economy in space is required** John Walter Gibbs, 6, Lord-street, Liverpool.

12836. **Improvements in automatic electric cut-outs.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Electrical Works, Salford, Manchester. (Complete specification.)

12869. **Improvements in or relating to automatic electric time calls.** Joseph Lapish Jack, jun., 45, Brook street, Shadwell, London.

12871. **Improvements in electrical circuit closers.** Charles Ambrose McEvoy, 24, Southampton-buildings, Chancery-lane, London.

12888. **Improvements in electric arc lamps.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Jacob Einstein and Sebastian Kornprobst, Italy.)

12893. **Improvements in signal apparatus in combination with tumblers, switches, and switchboxes.** Frederic Barry Stanton, 11, Queen Victoria-street, London.

JULY 4.

12953. **Manufacture of chloride of lead.** The Chloride Electrical Storage Syndicate, Limited, and John Gustaf Adolf Rhodin, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12954. **An improvement in secondary voltaic batteries.** The Chloride Electrical Storage Syndicate, Limited, and George Annesley Grindle, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12962. **Improvements in electric lighting for vehicles.** Jules Albert Ageron, 18, Buckingham street, Strand, London.

JULY 5.

13014. **Improvements in dynamos and electric motors, the invention being particularly applicable to motors carried in the rudders of vessels.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

JULY 6.

13090. **Improvements in electrolytic cells.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

13091. **Improvements in electric switches.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

13113. **Improvements in telephonic installations.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Ed. Baivy, Belgium.)

SPECIFICATIONS PUBLISHED.

1886.

17018. **Transmitting electric currents in electric rail, etc., systems.** Smith. (Second edition)

1894.

5537. **Electrical deposition of zinc, etc.** Heathfield and Rawson.

7205. **Electro-deposition of aluminium, etc.** Gomess.

12552. **Protecting electric cables.** Nisbett.

12707. **Electric lampholders, etc.** Verity.

13148. **Electrical measuring and recording instruments.** Harrison.

21330. **Galvanic batteries.** Hübner.

1895.

52. **Electric lighting apparatus for railway cars.** Biddle.

4120. **Electric heaters.** Meek.

4610. **Secondary batteries.** Boese.

5313. **Ohmmeters, etc.** Crawley and Soames.

5331. **Recording wattmeters.** Devonshire. (Fish.)

5701. **Arc lamps.** MacIntire.

9056. **Safety appliance for electric circuits.** Siemens Bros. and Co. (Siemens and Halske.)

NOTES.

Society of Arts.—The council of the Society of Arts have elected Major-General Sir John Donnelly, K.C.B., as chairman of council for the ensuing year. The various committees have also been reappointed.

Personal.—Dr. Barton, of the physical department of the Nottingham University College, has been elected to a fellowship in the Royal Society of Edinburgh, upon the nomination of Lord Kelvin.—Herr Sarasin, director of the electrical experimenting station in Munich, has been appointed controller of the electrical section of the Berlin Industrial Exhibition for 1896.

Electric Organs.—M. Julien Lefèvre begins in *L'Electricien* of July 13 a series of articles, of which the following are some of the sub-titles: "Inconveniences of Mechanical Organs"; "Advantages of Electric Organs"; "The Principle of Electric Organs"; "Historical *Résumé*." An excellent engraving in the first article shows the electric organ in the Church of Saint-Clément at Nantes.

French Submarine Telegraphs.—The *Revue Scientifique* states there are three French companies having submarine cables—namely, the French Telegraph Company, from Paris to New York, with 4,080 miles; the Commercial Cable Company, with seven cables having a total length of 10,495 miles; and the French Society of Submarine Telegraphs, with 15 cables of a total length of 5,260 miles.

Platinum.—The entire platinum output of the Ural Basin, a foreign journal announces, has been sold at very high prices for 10 years ahead. Some years ago this metal cost 2,700 roubles per pood of 36 English pounds. In 1893 an English firm acquired the decadal production of the Tagil Mines at the price of 8,000 roubles per pood. Now a French electrical company has concluded a contract with the remaining Ural mines for the supply of the 10 years' output at the rate of 12,500 roubles.

The Hermite Process.—Major Ruck, R.E., and Dr. Tyndall, from Netley Hospital, have visited Ipswich for the purpose of officially inspecting the Hermite electrical installation now used in the treatment of the Ipswich sewage. Mr. H. J. W. Jervis was deputed by the Mayor to receive the visitors, who, under the guidance of Mr. A. E. Cooper (of the firm of Paterson and Cooper, the engineers), thoroughly entered into the details of the process, and took practical observations upon the results of the treatment, expressing at the conclusion of the visit their appreciation of this system of dealing with the sewage.

Landslip on the Snaefell Electric Railway.—On Friday a workman on the Snaefell Electric Railway named Wm. Tate was engaged in loosening soil, when a large landslip unexpectedly occurred. It completely buried the unfortunate man. The work of extraction was proceeded with as soon as possible, and Tate, who suffered from serious injuries, was removed home. Dr. Miller pronounced the injuries too serious for immediate examination, the chest was badly crushed, hemorrhage was very extensive, the lower part of body was partially paralysed, and there are bruises about the head and face. Tate lies in a critical condition. This is the third serious accident that has befallen this unfortunate man.

The Baule Electric Log.—M. Baule, a retired naval officer commanding the Messageries Maritimes' vessel "La Plata," has devised an electric log which has attracted considerable attention in France. In this new instrument M. Baule returns to the helix, the surfaces of the four comparatively thick copper blades of which are, nevertheless, quite plane. The helix is not attached to the tail of the log, as in the apparatus of M. de Tromelin, but, like the English Massey, Walker, and Garland logs, is towed by a cord, the torsion of which actuates a box-counter, which is either submerged or kept on the sheer-rails. M. Dary, in *L'Electricien* of June 29, says that the French navy now has two electric logs, the qualities of which appear at the moment to be equal—the Fleuriais spoon-mill and the Baule screw instrument.

Electricity v. Gas.—Mr. J. Blacket Gill, who presided at the general meeting of the European Gas Company, Limited, held on Monday at Finsbury House, stated that they could not help being struck with the great inroads which electricity had already made among their consumers, for there were rarely shops of any standing at all which had not got the electric light. There was no doubt that the only way of competing with electricity was to make the price of gas as low as possible; but in the case of their own company this was not such an easy matter, as they worked under very different conditions from London companies. Their company had concessions, and most of the municipal authorities whose towns were lighted by the company were glad to have a "finger in the pie." They could not, therefore, charge as low a price as they would wish, as they had to pay considerable sums to the authorities.

The Electrophone. — We are informed by the Electrophone, Limited, of Shaftesbury-avenue, W., that the "eloquence of Dean Farrar on the occasion of his farewell address will not only reach his devoted congregation at St. Margaret's, Westminster, but his utterances, which cannot but be most impressive, will at the same instant be transmitted through the electrophone to his hosts of admirers in other districts of London, and probably to hospitals, thus enabling the invalided and those unable to be present for want of room and other reasons to avoid missing an intellectual discourse. St. Margaret's, Westminster; St. Anne's, Soho; St. Martin's-in-the-Fields; St. Michael's, Chester-square; the Highbury Congregational, Marylebone Presbyterian, and Christchurch, Birmingham, etc., are the churches amongst the leaders in this interesting and benevolent movement." The communication is dated the 15th inst., but the date of the function has not been vouchsafed by the company.

A New Use for Accumulator-Chests. — The Belgian Customs authorities have discovered an ingenious smuggling trick. In the luggage-van of the express which runs between Paris and Brussels is a case which holds the accumulators when the train is electrically lighted. The guard of the express, a foreman porter, and an excise official of the border station Quèvy possess a key of this case, which, as a rule, no one thinks of examining. The other day, however, as the train ran into Quèvy, a Customs inspector took it into his head to open the chest, and to his amazement he found snugly ensconced therein watches, chains, rings, bracelets, and other dutiable jewellery to the value of 7,000f. The guard and the foreman porter were quietly but firmly detained in Quèvy pending enquiries, which ultimately showed that the porter had for a long period been carrying on a contraband traffic for a well-known jeweller, who, it is said, will be a heavy sufferer by the disclosure of his frauds on the Customs officials.

Long-Distance Telephony.—On Tuesday the trunk telephone wires from London to Edinburgh, Dublin, and other important towns were opened for use by the public. Subscribers of the National Telephone Company in London can make use of the wires through the company's exchange system, and the wires can also be used by members of the

Digitized by Google

public at the call offices—at the General Post Office West (corner of Bath-street), the Threadneedle-street (Stock Exchange) Branch Post Office, and the West Strand Telegraph Office (Charing Cross). The wires were fairly patronised by the public, and the Post Office authorities entertain the idea that the new institution will be highly successful. They are under the impression, however, that for effectual long-distance speaking it is necessary to employ double wires, as the single-wire system cannot conduct the sound of the human voice so clearly as is desired. This remark applies to those companies who are anxious to join the Post Office in developing the trunk system.

Automatic Marine Fog-Signal.—A new design of automatic marine fog-signal, the invention of Mr. F. H. Berry, of 14A, Clerkenwell-green, has been fitted to the British India Steam Navigation Company's steamship the "Dunera." The object of the apparatus is to give automatically, at the regular interval required by law, in case of fog, the whistle or bell signals. On the bridge of the vessel is mounted a switch, by turning which the officer in charge can divert an electric current to either the whistle or the ship's bell; the latter, of course, being sounded if the ship is at anchor, and the former when she is under way. The proper interval between the sounds is obtained by clockwork placed in the chart-house, or some other convenient position. The current is generated by means of batteries, the clockwork completing the circuit at the necessary intervals, and in this way electrical energy is obtained for either striking the bell or opening the valve of the whistle. At the same time that the whistle is blown or the bell sounded, a pen is brought into contact with a continuous band of paper, which is marked with divisions. As the paper is wound off at a uniform speed by the clockwork an autographic record is obtained showing when the fog-signals, by bell or whistle, are sounded.

Code Messages.—There is much dissatisfaction at the contemplated enforcement of the Berne "official" vocabulary for code telegraphic messages, and this dissatisfaction, says the *Financial News*, has now been voiced by the New York Coffee Exchange. Its grounds for opposing the compulsory use of the code are (1) that there is no apparent good reason for interference with the existing liberty to employ any word found in the dictionaries of the eight authorised languages; (2) that the proposed official vocabulary is, in various ways, exceedingly faulty; (3) that the contemplated change appears to have been brought forward more to avoid a little occasional trouble for telegraphic officials than to facilitate the work of those who transmit messages; (4) that the necessity for the repetition of doubtful words is likely to be as frequent as it is at present; and (5) that the enforcement of the new vocabulary means the extinction of present codes and their reconstruction and reprinting at enormous expense, not to speak of the great inconvenience occasioned pending the change. The resolutions have been forwarded, it is understood, to the New York managers of the cable companies, with a request that they may be laid before the permanent authorities of the International Telegraph Conference, the next meeting of which is to take place at Budapest in 1896.

Electrically-Lighted Buoys in New York Bay. Incandescent electric lamps on spar buoys have been experimentally used in New York Bay for several years, but an installation has now been completed which marks a considerable advance in maritime engineering and renders the entrance to New York Harbour possible for the largest vessels at any hour of the night. Gedney's Channel, which is the course taken by the Transatlantic steamers, is only 1,000ft. wide, and while buoyed by day, became an impracticable course at night. It is now lighted by 10 incandescent lights of 100 c.p. each, placed on the top of spar buoys on each side of the channel, forming a lighted avenue for the shipping. The lamps are mounted on 50ft. cedar buoys which are shackled to 5,000lb. mushroom anchors. The cable is constructed of a copper conductor, insulated with guttapercha, then bedded with jute and sheathed with an armour of hard-drawn copper wires. This cable carries successfully, according to the *Engineering Record*, an alternating current at a pressure of 1,000 volts under water for a distance of 6½ miles. The generating station is located about 2,000ft. from the beach. The current for lighting the buoys is carried to the submarine cable through a lead-covered conductor laid in a creosoted subway 4ft. underground. The electric plant is in duplicate. The current is generated at 100 volts and is raised by a step-up transformer. All the high-tension lines are either underground or in cables at the bottom of the sea.

Science Research Scholarships.—Her Majesty's Commissioners for the Exhibition of 1891 have made the following appointments to science research scholarships, for the year 1895, on the recommendation of the authorities of the respective universities and colleges. The scholarships are of the value of £150 a year and are tenable for two years (subject to a satisfactory report at the end of the first year) in any university at home or abroad, or in some other institution approved of by the commissioners. The scholars are to devote themselves exclusively to study and research in some branch of science, the extension of which is important to the industries of the country. University of Edinburgh, John D. F. Gilchrist, M.A., B.Sc.; University of Glasgow, Walter Stewart, M.A., B.Sc.; University of St. Andrews, Henry Charles Williamson, M.A., B Sc.; University College, Dundee, James Henderson, B.Sc.; Mason College, Birmingham, Robert Howson Pickard*; University College, Bristol, Samuel Roslington Milner*; University College, Liverpool, John Taylor Farmer, B.Sc.; University College, London, Emily Aston, B.Sc. Owens College, Manchester, William Henry Moorby, B.Sc.; Durham College of Science, Newcastle-on-Tyne, Alexander Lawson Mellanby, A.Sc.*; University College, Nottingham, Martin Ernest Feilmann; Queen's College, Belfast, William Hanna, M.A.; McGill University, Montreal, Robert Owen King, B.Sc.; Queen's University, Kingston, Canada, Thomas Leonard Walker, M.A.; University of Sydney, John Alexander Watt, M.A., B.Sc.; University of New Zealand, Ernest Rutherford, M.A. * Conditional appointments.

Transformer-Chambers in the Streets.—The Highways Committee of the London County Council on Tuesday reported that the County of London and Brush Electric Lighting Company had asked the Board of Trade to give a definite decision upon the appeals of the company which were the subject of an enquiry by the Board of Trade in December. On February 24 they reported that the Board had intimated that it was not prepared to hold that sufficient reasons had been advanced, either on the ground of public safety or of want of parliamentary sanction, to justify the Board in refusing to approve of a system of supply involving the use of transformer-chambers in the public streets, and that the Board hoped that this decision on the general question would render unnecessary any further action on the appeals lodged by the company. The Board afterwards approved a description of the system of supply under the County of London (North) Order, 1892, which contained the following words: "The converting stations

Digitized by Google

will be street boxes of sufficient size and suitable construction to contain several transformers, room being also provided to enable a man to enter the box and conveniently examine the transformers and controlling apparatus." The Board of Trade had decided to hold a further enquiry into the matter, at which it was thought desirable that the Council should be represented by counsel. The Council adopted the recommendation of the committee that they should be authorised to take all necessary measures for making known at the Board of Trade enquiry the Council's objections to the transformer-chambers being placed under the public streets.

Electric Light Station in Shanghai.—The new electric light station which the Municipal Council of Shanghai are erecting at the corner of Yuheng and Fearon roads is, says the *Shanghai Gazette*, of bold and handsome proportions, its design having evidently been to combine a striking exterior with internal adaptability to the purpose for which the edifice is intended. The building throughout is constructed of blue and red brick, and the most striking feature about it is, of course, the tall chimney, which will be the largest in Shanghai, measuring 120ft. in height, with an internal diameter of 7ft., the outside diameter at the base being 20ft., from which it will gradually taper to 13ft. at the top. The engine-house measures 116ft. in length, 85ft. in breadth, and 25ft. in height. It is intended to place no fewer than 14 compound horizontal surface-condensing engines by Marshall and Co., of Gainsborough, whose machinery seems to be growing in popularity in China, there being now, our contemporary states, some 40 engines manufactured by them working in Shanghai alone. The dynamos for arc lighting are by the Brush Company, of Cleveland, Ohio, U.S.A., and the alternators, switches, transformers, and such instruments are the work of the Brush Company, of England. The boiler-house is also a very spacious and lofty apartment in which will be placed three Lancashire boilers, each measuring 7ft. by 28ft., and capable of sustaining a daily working pressure of 140lb. These three boilers are the largest of the description in Shanghai. There will also be two locomotive boilers working at the same pressure. Adjoining the electric light station are two airy dwelling-houses for the superintendent and assistant superintendent. The superintendent's office and workshop adjoining will be fitted with all of the most modern electrical appliances. All the buildings are roofed with galvanised corrugated iron, with the exception of the dwelling-houses, which are roofed with Marseilles tile.

The Campden Technical Institute.—On Tuesday, on a piece of ground adjoining the public library in Lancaster-road, North Kensington, the foundation-stone of a new technical institute in connection with the Campden Charities was laid by Princess Louise, Marchioness of Lorne. On the platform, over which a prettily-decorated marquee had been erected, were the Rev. the Hon. E. C. Glyn (chairman of the Building Committee), who presided, Mr. Wyndham Gibbes (deputy-chairman of the Building Committee), Sir Algernon Borthwick, Dr. Gladstone, Canon Trench, Mr. William Bousfield, and others who have interested themselves in the movement. It appears that the building is to be on a site purchased for £2,526, mainly defrayed from money subscribed in response to an appeal by the Marquis of Lorne. As the amount given by the public in Kensington was insufficient to complete the purchase and to erect a polytechnic institute, the Campden trustees, with the consent of the Charity Commissioners, granted the sum of £5,000 for the purpose. As soon as the institute is completed, the evening classes in woodwork, wood-carving, drawing, dressmaking, and cookery now maintained by the trustees in North Kensington, and at present meeting in different places, will be moved into the new building, and it is hoped that further donations from the inhabitants of Kensington will enable the trustees at some future time to add a gymnasium and other manual and technical classes. There is at present no polytechnic institute within reach of the crowded working-class district of North Kensington, and the trustees are unable to create out of their funds an organised polytechnic similar to those existing in other parts of the Metropolis. The building is to be two storeys in height, and in red brick, with stone dressings. The whole of the ground floor is to be set apart for the boys, and the first floor for the girls. The architect (honorary) is Mr. Rowland Plumbo, of Fitzroy-square. In addition to laying the foundation-stone, Princess Louise, who met with a hearty reception from a large crowd on her arrival and departure, gave away the prizes gained by the girl students attached to the polytechnic.

The Metric System.—In answer to the questions sent out by the New Decimal Association, Mr. C. S. Smith, British Consul at Bilbao, in his commercial report for the year 1894 observes: "I have spoken to a good many people on this subject. Although everyone feels that the difference of units is a difficulty in the way of trade, and therefore must have the effect of in some measure reducing its volume, no one has been able to name a single specific case where the difference has prevented an order from being given to an English firm. The difficulty appears to me to be of the same nature as that presented by differences of language. I do not gather that it is contended that British goods are made of sizes that are not required, only that they are described in measures which are not understood by purchasers. The proposal is to change the way of describing the articles to be sold, not their dimensions. If I wrongly understand the contention, I would point out that the dimensions of the goods are independent of the standards used to describe them, and it may be supposed that any required size of goods could be manufactured without first adopting the decimal system. If, on the other hand, it is desired to overcome the difficulty of making our measures intelligible to the foreign purchasers, and to avoid waste of time and labour in conversion, it might be observed that the use of tables makes conversion quick and easy, and that there seems to be no reason why price lists should not be made out so as to give metric equivalents to dimensions in English measures, exactly as at present lists are made out which give Spanish names and descriptions for British goods. Firms which would take the trouble of doing this would be able to report whether they have gained any considerable increase of customers from it, and this experience would help the future consideration of the question. I have been asked to treat this matter from the point of view of foreign trade. I am bound to say that, as far as my enquiries go, foreign trade does not furnish adequate reason for the British Empire to undergo the inconveniences of making the change. So as not to be misunderstood, I should add that my personal vote would be for the change, even though the metre be not what it was once supposed."

High Speed of Electric Motors.—Some interesting trials on the Nantasket branch of the New York, New Haven, and Hartford Railroad took place on June 20 and 22. The Nantasket Beach branch was chosen for the experiment for the reason than within its limits will be included most of the different problems which will have to be determined to make electricity a successful substitute for steam. The curves are many and sharp, the grades are

Digitized by Google

steep, and trains will be run with great frequency. Seven miles is the distance between the Old Colony station and Pemberton. The tracks are 15ft. apart from centre to centre, and between the tracks is a single line of poles on which are supported the cables and trolley wire. Upon the tangents the poles are set with such geometrical precision as to secure absolutely perfect alignment. The two flexible copper bonds, 7in. long, are under the base of the rail at each joint and riveted to each rail. A power-house, No. 1, is situated midway between the terminals and contains two tandem compound engines; the two generators develop 1,500 h.p. each. Four motor cars have been built after the style of baggage cars. To secure traction they have been made extra heavy, so that when fully equipped they will weigh about 60,000lb. each. Two will have four motors each and the other two motors each hung on trucks. The cars are equipped with the Westinghouse air-brake, and in addition to a 15in. gong there will be a chime whistle worked by compressed air. The test was held in the presence of only a few invited guests. There was none of the gradual increase of speed characteristic of the steam locomotive. A test was made of a load of 175 tons, equal to a train of seven cars, but the ease of starting and the speed obtained showed that a load of three or four times as great could be easily drawn. A speed of more than 50 miles an hour was obtained, and for a part of the distance it was estimated that the train made at times the enormous speed of 80 miles per hour. A hot box prevented a greater increase of speed. When the train was making 80 miles an hour there were still five notches left in the "controller" in the motor, so that if the additional current had been applied, it is thought that a speed of 90 miles an hour might have been obtained on the level stretches.

Thermo-electric Properties of Pure Metals.—Herr K. Noll, in *Ann. Phys. Chem.*, states that, owing to considerable differences between the observations of different workers on the thermo-electric properties of metals, he redetermined the E.M.F. for various combinations, employing metals in as high a state of purity as was obtainable. In the first series of experiments the second metal was in all cases mercury and the temperatures of the junctions 100deg. and 0deg. The E.M.F. was determined by Du Bois Raymond's modification of Poggendorf's methods, Clark cells being employed as the source of the constant E.M.F. The results of these researches (expressed in microvolts) are contained in the following table, + values indicating a current from mercury to metal at the hot junction:

Bismuth	−6,705·4	Carbon rod ...	+ 662·88
Nickel	−1,664·2	Silver	+ 710·25
Cobalt	−1,522·2	Gold	+ 713·35
Nickel silver	−1,085·2	Copper.....	+ 725·58
Platinum.....	+ 4·59	Zinc	+ 692·71
Aluminium...	+ 362·4	Cadmium.....	+ 875·09
Magnesium...	+ 391·84	Carbon filament	+1,452
Tin	+ 396·03	Iron	+1,601·4
Lead	+ 402·5	Piano wire ...	+1,732·3
Brass	+ 443·31	Antimony ...	+3,379·6

In many cases the effect of small quantities of impurity was very great. Thus platinum gave values as high as +593·88 and copper as low as +684·29 when the metals were not chemically pure. The state of aggregation had also a marked effect in some cases—for instance, silver (710·25; 671·51), zinc (692·71; 735·2), iron, brass, nickel. The second series of experiments was performed at various temperatures between 217deg. and 0deg., a number of experiments being made in each case. From the results the value for 100—0deg. was calculated, good agreement with the observed value being in all cases obtained. The junctions were in some cases formed with mercury, in others with copper. The E.M.F. is given according to Gaugain by formula $\epsilon = (t_1 - t_2)\{b \pm c(t_1 + t_2)\}$. The values for b and c are deduced from two experiments, and the results calculated by their aid compared with the observations. The agreement is perfectly satisfactory. The value $\frac{d\epsilon}{dt} = b \pm ct$ is then calculated, and as this can be expressed as $b \pm (k_2 - k_1)\,t$, where k_2 and k_1 are the constants for the different metals of the junctions, the numbers are referred to lead, for which $k = 0$. The values thus obtained for the thermo-electric power $\frac{d\epsilon}{dt}$ are compared with those of other observers. The difference in the result may be explained by the effect of impurities which, as is evident from the numbers, produce considerable variations.

The Chronoscope.—It is stated that what is claimed to be the most wonderful timing instrument in the world was exhibited before the members of the Department of Pedagogy and Psychology of the Brooklyn Institute of Arts and Sciences recently. It is called a pendulum-chronoscope, and has excited widespread interest in the scientific world. It measures accurately down to the one-thousandth part of a second, and is expected to take the place at once of the old-style chronoscopes in scientific laboratories. The idea of the instrument was originally suggested by Prof. Charles B. Bliss, of the School of Pedagogy of New York University. The machine was made and perfected by Mr. J. J. Hogan, the head of the mechanical department of the Psychological Laboratory of Yale. It can be used with the quickness of a stop watch, and neither electrician nor mathematician is needed as operator. Constructed on the pendulum principle, it measures the reaction time between sight, hearing, or the operation of the will in muscular movement. The instrument is a mechanical one, with simple electrical attachments. The speed of a cannon-ball can be determined by the new timer, and it will tell the lapse of time between the firing of a revolver and the starting of a runner, or determine how long it takes a boxer to deliver a blow. The new instrument is about 2ft. high, and is mounted on silver and nickel. It costs about £40 to construct it. A simple description of this machine is that it consists of a pendulum and a pointer swinging independently on the same axle. The tip of the pointer swings along the face of a curved scale or indicator, which is so graduated that it shows the one-thousandth of a second. To measure the time required for the transmission of any given impression a button is pressed, and this sets the pendulum in motion and registers the result on the scale. It has been demonstrated that on an average the reflex action for sound occupies 0·130 of a second. In making a sight test when the pendulum comes in contact with the pointer a black shutter is raised from a light disc. As the disc flashes on his sight the subject touches the button and the pointer is at once stopped. It has been found that 0·300 of a second is the average time between the exposure of the disc to the sight and the pressure of the button. A test for discrimination is to exhibit from behind the shutter a square of some colour. The person operated upon does not know what colour may be exhibited. He is told, for instance, to press the button when he sees blue. Such a test will involve a longer time, perhaps the one-fourth of a second altogether. Other trials are made with odours, sounds, or pin-pricks. An Italian machine for making these tests is moved by clockwork and exhibits the results upon two dials, the one marking hundredths and the other thousandths of a second. The value of these tests for the purposes of the School of Pedagogy is to enable teachers to know what the mental characteristics of their

Digitized by Google

scholars really are. Under the system of teaching of a generation ago no one paid any attention to this in dealing with pupils. Schoolmasters in those days, in fact, did little or nothing in the way of teaching. The routine of a school then consisted in a master's telling his classes what pages of the books the lessons for the next day were to be found upon, how long the lessons would be, and hearing the scholars recite.

Condensation of Electrolytic Gas.—Messrs. Louis P. Caillett, Emmanuel Collardeau, and Marcellin Berthelot, in *Comptes Rendus*, describe the condensation of electrolytic gas by porous substances, especially by metals of the platinum group. Spongy platinum was enclosed in two small silk bags, together with a platinum wire to serve as a conductor, and immersed in dilute sulphuric acid (1 : 10), one bag forming the anode and the other the cathode. An electric current was allowed to pass until the platinum was presumably saturated with the two gases, and the two bags were then placed in electrical communication so as to form a gas battery similar to that of Grove. Under these conditions a much more powerful and persistent current is obtained than with the same weight of platinum in the ordinary metallic condition, and the duration of the current is greatly increased under pressure. Under atmospheric pressure the discharge lasts only about 10 seconds and the E.M.F. falls continuously from 1·8 volts to zero. Under gradually increasing pressure the manner of discharge gradually alters and three periods are recognisable. There is first a period of very rapid fall in the intensity of the current, which afterwards rises slightly; this is followed by a period of constant intensity, the intensity slightly increasing with the pressure, and the E.M.F. being about one volt; finally, there is a period of fall less rapid than the first. The capacity of the accumulator thus formed by the spongy platinum is 56 ampere-hours per kilo. of metal under a pressure of 580 atmospheres, and the intensity of the current may easily reach 100 amperes per kilo. In order to obtain the best results, about three times as much platinum should be used for the negative pole as for the positive. The yield of the accumulator is as high as 95 or even 98 per cent., provided that the charge is not pushed to its limit, and that the discharge begins immediately after charging. Iridium behaves like platinum; ruthenium is slightly attacked at the positive pole, but will also form an accumulator with a capacity that increases with the pressure, but with an E.M.F. that is not constant but decreases continuously from 1·6 volts to zero, whatever the pressure. Palladium in the metallic form constitutes an accumulator of very feeble capacity, owing to the rapidity with which it is saturated by oxygen; but in a spongy condition it gives results much better than those obtained with any other metal of the platinum group, and even under atmospheric pressure is equal to platinum under a pressure of 20 to 30 atmospheres. As the pressure increases the phenomena are similar to those observed with platinum, but the capacity of the accumulator is three or four times as great, and under a pressure of 600 atmospheres may reach 176 ampere-hours per kilo. Gold precipitated by sulphuric acid behaves like the platinum metals, but the capacity is lower and the intensity of the current varies somewhat differently. Silver, tin, nickel, cobalt, and carbon undergo change at the positive pole, and although there is some accumulation of electrical energy, it is not affected by pressure and seems to be due to chemical changes. Berthelot points out that platinum, palladium, and analogous metals form definite compounds with oxygen, and especially with hydrogen, at the ordinary temperature, their formation being influenced by pressure.

The Mulhouse Industrial Society Prizes.—Unlike some other French and German institutions, the Société Industrielle de Mulhouse opens its prize competitions to foreigners. Among the premiums offered by the society for 1896 are the following: A silver medal for an application of electricity in the printing industry.—A silver medal and the sum of 500f. for the invention and application of a pyrometer for registering the temperature of the gaseous products of the combustion of coal in boiler furnaces. An instrument is required capable of indicating to within 5 per cent. the temperature of a gaseous current between the limits of 300deg. and 800deg., the apparatus itself to be in the midst of the gases, the temperature to be read outside the furnace. The prize will only be awarded to an instrument which has been in use for at least six months in connection with a steam-boiler in Upper Alsace. — Medal of honour for a practical installation in an Upper Alsatian industrial establishment for distributing motive power to a plant through an electrical network fed from a private or public central generating station. The installation should have been working for a year in Upper Alsace; and it should, among other advantages, be appreciably cheaper than the distributing method hitherto employed. The medal will be granted not only to the inventing engineer but also to the establishment in which the installation was carried out.—Medal of honour for a 10-h.p. electric motor capable of developing a variable energy and speed at will.—Prize (to be afterwards fixed) for a new, simple, and practical method of fixing armature wires to the commutators. The new system should allow of the easy changing of the collectors and facilitate, if possible, the investigation of faulty insulation of the armature wires; and should assure a good contact of the wires with the bars of the commutator. The application of the new method to any kind of drum or cylindrical (Gramme) ring is to be dealt with. The treatise should enumerate the advantages and disadvantages of the present systems and compare them with the new method proposed.—Medal of honour for a memoir treating of the comparative cost of an electric and a gas installation, both required to supply light to a town of at least 30,000 inhabitants. The comparison should deal particularly with the following points: (1) cost of the central station and of the gasworks, of the electric distribution and of the gas-mains, of the domestic fittings; (2) cost of the coal essential for the production of power at the central station and the gasworks; (3) cost of working and maintenance in the two cases. A special chapter should be devoted to a detailed account of the resulting expenses and receipts—in the case of the gasworks the value of the by-products to be taken into consideration. Another chapter should treat, being based upon a fair number of experimental determinations, of the photometric value of gas-burners of a given consumption and of the electric lamps which are usually substituted for them.—Silver medal for a treatise on the comparative cost of an electric and a gas installation, of at least 300 lamps, both required to furnish light to an industrial establishment. The different kinds of electric lighting should be dealt with, and the cost of working compared with that of a gas installation. A special chapter should be devoted to a comparison of the intensities of light obtained in the various instances. All treatises, drawings, models, etc., should be marked with a motto, and forwarded before February 15, 1896, to M. le Président de la Société Industrielle de Mulhouse, together with a sealed letter containing the full name and address of the competitor. Anyone may obtain a copy of the programme of the prizes to be grant by applying to the Secrétariat of the society.

ON A METHOD OF DETERMINING THE THERMAL CONDUCTIVITY OF METALS, WITH APPLICATIONS TO COPPER, SILVER, GOLD, AND PLATINUM.*

BY JAMES H. GRAY, M.A., B.SC.

Communicated by LORD KELVIN, P.R.S.

(Concluded from page 41.)

The calorimeter ball most frequently used in the present work was turned from the solid, and is 5·5cm. in diameter. This was found to be a very convenient size for the metals of high conductivity—for example, gold, silver, and copper. Any length from 4cm. to 8cm. of wires of these metals may be used without making it difficult to read the rise in temperature per minute. It is not advisable to use lengths shorter than 4cm., as there is then a danger of the water-jacket being too near the heating-box, but it is better to use a smaller ball, say, of 4cm. diameter, for metals of lower conductivity. For metals having conductivities between 1·0 and 0·7 C.G.S. units, the large ball was found to be quite convenient; for lower values the smaller ball was used. The object aimed at was to arrange the dimensions so as to enable an experiment to be finished in less than half an hour from the time that one end was made hot by the boiling water.

After the wire has been soldered in, the box is placed in the screen, L (Fig. 2), and fixed by any convenient means, so that the wire hangs vertical, and the asbestos cover is put over the box. The cardboard tube, having been made of suitable length, and slit along its length, is now slipped round the wire, and, after a little cotton is loosely packed in, the slit is closed up by means of a strip of gummed paper. The wire is now completely enclosed in this tube and loosely surrounded by cotton wool.

The thermometer is placed in the hole in the ball, and a little water put in to fill up the hole. The water-jacket may then be raised so as to surround the ball, and the top of the water-jacket must be covered with two or three sheets of paper, holes having been cut in these, so as to admit the wire and thermometer.

It was found best to make these preparations a few hours before the actual test was begun, so as to allow the system to take up a permanent temperature. When it has been ascertained that this temperature has been reached, a reading is taken from the thermometer in the ball. The thermometer used was most carefully made and calibrated for the tests by Mr. Otto Müller, of Glasgow. The whole length of the stem is 15cm., and it is marked off to read twentieths of a degree from 9deg. to 20deg. C. Each division is ½mm., so it is perfectly easy to read to one-fortieth of 1deg.

Before beginning the test the water-jacket is lowered, and a vessel containing ice and water raised so as to cover a part of the ball. By this means the temperature of the ball is lowered by 6deg. or 7deg. below that of the air. While this is being done, the boiling water is poured into the box, so as to nearly fill it, and the Bunsen lamp lit. The water soon begins to boil rapidly, and the thermometer (which is 12cm. long and reads from 95deg. to 105deg. C.) indicates a constant temperature, usually 97deg. or 98deg. C. When the temperature of the ball has been lowered 6deg. or 7deg., the ice and water are taken away, and the ball is carefully dried with a soft cloth. The water-jacket is again placed so as to surround the ball and the cover put on as before, the circulation of water in the jacket having been started.

It is now only necessary to take readings of both thermometers every half-minute. The temperature of the hot water will be practically constant, but it is advisable to take the readings in case of alteration. The calorimeter thermometer may be read till it reaches 20deg. C.

It will be convenient to explain here the reason for cooling the ball 6deg. or 7deg. before starting. In the preceding remarks no notice was taken of the fact that there will be radiation to or from the surface of the ball unless the latter is at the same temperature as its surroundings. It would be impossible to allow for this by calculation, as the surface is altered before every test by being heated while the wire is being soldered into the ball. For the purpose of getting rid of the necessity of allowing for this radiation the ball is cooled.

Let Q_1 = the quantity of heat which flows along the wire in unit time when the hot end is at T degrees and the cool end at θ degrees above the temperature, t, of the air and water-jacket, and let Q_2 = the quantity when the cool end is θ degrees below that of the air.

Then, assuming that the conductivity does not change very much through 2 θ degrees, and that α, the loss by radiation in unit time when the ball is θ degrees above the air temperature, is equal to the gain by absorption in unit time when the ball is θ degrees below the air temperature, we have

$$Q_1 = \frac{K A}{l}[T - (t + \theta)] - \alpha,$$

and

$$Q_2 = \frac{K A}{l}[T - (t - \theta)] + \alpha.$$

Therefore

$$\frac{Q_1 + Q_2}{2} = \frac{K A}{l}(T - t).$$

It is seen by the last equation that the effect of radiation to or from the surface of the ball is completely eliminated, since the coefficient of emission is numerically equal to the coefficient of absorption for the same difference of temperatures. It, therefore, fortunately does not matter how the surface of the ball becomes changed, so long as it remains the same during the half-hour of the experiment. As a matter of fact, during the soldering process the surface becomes very much tarnished. Table I. gives a specimen experiment taken at random from my laboratory book.

TABLE I.—Friday, March 23, 1894.—Pure Silver Wire (annealed). Length = 6·59cm. Diameter = ·202cm. Temperature of air = 14·3deg. C.

14·6	98·3		

The numbers in Column I. are put on a curve, as shown in Diagram II. From this curve the rise in temperature in half a minute is read off for x degrees above the temperature of the air, and this is added to the rise for x degrees below the temperature of the air, where x is any value from 0 to 5 or 6. In this way as many as 10 or 15 values are obtained. If the curve were quite regular, each of these values would be the same, since they each represent the rise in temperature per minute for the same difference of temperature, but they are found to vary by about 1 or 2 per cent. But by taking the mean of 10 or 15 values, it will be seen that the result obtained must be very near the correct value for the rise between the given temperatures. It is then only necessary to multiply this rise in temperature by the thermal capacity, C, of the ball to find the quantity of heat that has passed along the wire in one minute, and the conductivity can be calculated from the formula

$$K = \frac{C\,\theta\,l}{\pi r^2 (T - t)\,60},$$

where r is the radius of the wire.

In order to obtain an accurate determination of the thermal capacity of the ball, I took it to Dublin, where the capacity was most carefully determined for me during the time I was there by Dr. John Joly, F.R.S., by his most ingenious steam calorimeter method.* I have to thank Dr. Joly for the trouble to which he put himself in making the determination.

As the most important thing in testing the method is to show that with different lengths the resulting determination of the conductivity remains practically the same, these series of tests and the results will be given first.

The wire first used was what was called six years ago high electrical conductivity copper. The diameter was 2·1mm., density 8·85, volume specific (electrical) resistance, 1834 in electromagnetic units. This wire was almost exclusively used, but in the course of the work tests were made of wire got from Messrs. Glover and Co. in the end of the year 1890. Messrs. Glover's wire was found to have considerably higher conductivity, both electrically and thermally, than the first-mentioned wire, which for convenience will be called the laboratory copper, as it was what used for all the electrical work in the laboratory. Taking the laboratory wire as 100 per cent. conductivity (thermally and electrically), it was found that Messrs. Glover's wire was 106·6 per cent. electrical and 108 per cent. thermal conductivity.

These results will be referred to further on. They are merely mentioned here to show that the best conducting wire was not used for the exhaustive tests.

Table II. shows the record of series of experiments made on laboratory copper wire. The wire was soldered into the heating-box and ball as described; an experiment was made and the length measured carefully. The ball was then heated by a blow-pipe flame to allow the wire to be taken out. A short piece was then cut off and the shortened wire again soldered into the ball.

Temp. of air, 9°·85 C. Temp. of hot water 97°·3C.	Temp. of air, 9°·1 C. Temp. of hot water 97°·0C.	Temp. of air, 10°·0 C. Temp. of hot water 97°·0C.	Temp. of air, 10°·35 C. Temp. of hot water 96°·4C.	Temp. of air, 12°·3 C. Temp. of hot water 96°·7C.

The temperature of the hot water varied not more than ½deg. during an experiment, and the value given in each column of the preceding table is the mean throughout the time. The columns of temperatures were, immediately after an experiment, put on a curve with time as abscissæ. The effect of radiation to and from the calorimeter ball is fairly well marked. At the point corresponding to the temperature of the air in each curve there is an increase of curvature, caused by the fact that the radiation has changed from negative to positive.

In order to find the flow of heat, the rise of temperature per minute was read from the curve at a temperature $x$deg. below that of the air, and this was added to the rise for $x$deg. above that of the air. x varied from 0deg. to 4deg. or 5deg. By this means from 10 to 15 readings were got, and the mean of these gave the rise at the temperature of the air. For example, for the length 6·31cm. in the first column of Table I., the rise thus obtained from the curve, Diagram I., was ·3605 in one minute. The capacity of the ball and of the part of the thermometer with the water in hole was found to be 68·9.

There
$$K = \frac{68{\cdot}9 \times {\cdot}3605 \times 6{\cdot}31}{\pi \times ({\cdot}105)^2 \times 87{\cdot}45 \times 60}$$
$$= {\cdot}883 \text{ C.G.S. unit.}$$

This value is not corrected for the error given by the approximate formula already mentioned. Error:

$$= (V_1 - \theta)\frac{\frac{a}{2l}\frac{K}{k}\frac{b-a}{b}}{1+\frac{a}{2l}\frac{K}{k}\frac{b-a}{b}} \doteqdot {\cdot}69\text{deg. in this case.}$$

This makes the difference of temperature less by ·7deg., and when this correction is made we get for the conductivity ·889 C.G.S. unit. The conductivity as calculated from five different lengths becomes, after the correction is made—

Length in centimetres.	Conductivity.
6·31	·889
5·87	·893
5·23	·890
4·59	·887
4·015	·888

The greatest difference between these values is a little over 1 per cent. Taking their mean, we get for the thermal conductivity of the laboratory copper wire ·8884 C.G.S. unit. This value is the mean conductivity between the temperatures 97deg. C. and 10deg. C. The following table gives the results of a series of tests on another portion of the same wire:

Length in centimetres.	Conductivity.
6·11	·888
5·71	·883
4·80	·892
4·43	·889

The mean of these values is ·8880, being $\frac{1}{2\cdot3}$ per cent. less than that obtained from the preceding series.

Taking Angström's formula, $K = 1{\cdot}027\,(1 - {\cdot}00214\,t)$, and finding K for 53deg., which is the mean of 97deg. and 10deg., we get K = ·9208 C.G.S. unit.

The close agreement in the values obtained with different lengths shows that the errors already mentioned as possible are practically eliminated. Angström's value is 4·5 per cent. greater than ·8884, but, as has been mentioned, the conductivity of the laboratory copper wire is 8 per cent. less than that of Glover's wire afterwards tested. In a previous paper, Angström gives ·91 as the value for 51·3deg. C.

In a paper read before the Royal Society last year, Dr. R. W. Stewart, using the Forbes method, but substituting a single thermo-electric junction for the thermometers, gives the values for copper and iron. At the temperature 53deg. C. he gets for copper K = 1·067, which is 10 per cent. higher than the value obtained for any specimen of copper tested in the present investigation.

The conductivity of the wire obtained from Messrs. Glover and Son was found to be ·9594 C.G.S. This was the best conducting copper tested by the present method. The specific electrical resistance was 1,730 in absolute units. To test separately the effect of any alterations, separate experiments were made. Instead of enclosing the whole length of the wire (laboratory copper) in a tube, only a part was enclosed. The paper tube was shortened by 2mm. or 3mm. each time, and the conductivity of the same length of wire was determined after each shortening of the tube. The result found, was that the shortening (which was, of course, done from the cool end of the wire) had practically no effect on the value so long as it was arranged that there were no draughts of cold air. If for no other reason, the paper tube is necessary to prevent draughts, as the latter make a determination impossible. It was found that the paper tube could be shortened as much as to leave the lower half of the wire exposed without any appreciable diminution of the value obtained. When it was shortened much further the value began to diminish till, when the tube was removed altogether, the value obtained was found to be fully 6 per cent. lower than when the tube completely covered the wire. When the wire was bare it was found very difficult to prevent draughts caused by the hot wire, and these draughts made the readings of the thermometer very irregular. In connection with this it will be noted that there is a particular advantage in having the calorimeter ball lower in position than the heating-box, as the hot air round the latter rises, and so does not affect the water-jacket. It has been suggested, however, that a separate experiment should be made to test whether any heat

Digitized by Google

reached the ball otherwise than through the wire. For this purpose the ball was suspended by silk threads in such a way that its highest point was 4·4 centimetres from the bottom of the heating-box. The water-jacket was placed round the ball, and the sheets of paper put on the top of the jacket. The water in the heating-box was kept boiling for 25 minutes, and the temperature of the ball, as indicated by the thermometer in it, was noted at intervals. No change in the thermometer reading could be detected, although $\frac{1}{10}$th of 1deg. can be read without difficulty on the thermometer scale.

As a further test of the effect of the paper tube, the upper half length of the wire which was being tested was left unprotected by any tube, while the lower half was enclosed. The result was practically the same as if there had been no tube at all.

In order to make certain that the thermometer in the hot water indicated the temperature of the upper end of the wire, a thermo-electric junction was used. The junction was made of very thin wires of copper and platinoid, and, after being wrapped once round the hot end of the wire just at the end, was soldered there. The other junction was fixed to a thermometer and immersed in water. The heating-box was then filled with water, which was kept boiling. The water in the vessel containing the other junction was gradually heated up till there was no deflection in the mirror galvanometer used. Both junctions must then be at the same temperature. When there was no deflection in the galvanometer the thermometers were found to be indicating the same temperatures.

Several qualities of copper were tested, the results of which are given below.

Copper wire, made by Messrs. Bolton and Co., Cheadle, was by mistake sent away before its electrical conductivity was measured, and it cannot be got again.

Length used (in centimetres).	Mean conductivity between 10deg. C. and 97deg. C.
7·0	·867
6·33	·862
5·7	·859
5·1	·858

The greatest variation here is 1 per cent., and the mean value is ·8612.

Some specimens of copper wire were bought in a plumber's shop of quality used for bell-hanging.

Specimen.	Diameter (in centimetres.)	Specific resistance (electrical).	Mean thermal conductivity.
1	·200	5545	·3198
2	·204	4701	·3497

$$\frac{\text{Conductivity of laboratory wire}}{\text{Conductivity of specimen 1}} = 2{\cdot}78 \text{ for heat;}$$

$$= 2{\cdot}86 \text{ for electricity.}$$

$$\frac{\text{Conductivity of laboratory wire}}{\text{Conductivity of specimen 2}} = 2{\cdot}54 \text{ for heat;}$$

$$= 2{\cdot}56 \text{ for electricity.}$$

$$\frac{\text{Conductivity of Glover's wire}}{\text{Conductivity of laboratory wire}} = 1{\cdot}08 \text{ for heat;}$$

$$= 1{\cdot}066 \text{ for electricity.}$$

In all the wires tested it was found that if one metal was a better conductor for electricity, it was also better for heat. This has been noticed by several investigators, notably Prof. Tait, and Wiedemann and Franz. Beyond this the present results cannot go, as enough trials were not made to allow of comparison. Previous experimenters have found that the ratio of electrical conductivities of two wires is not exactly equal to the ratio of thermal conductivities. This is indeed to be expected, if the coefficients already obtained for the alteration with temperature are accurate. For example, in copper the coefficient of variation per degree for electrical conductivity is very much greater than that found for thermal conductivity, so that, even if the ratios were equal at one temperature, they must be unequal at all other temperatures. In some of the wires tested the electrical and thermal ratios differed by as much as 4 or 5 per cent.

Before the present investigation, the absolute values for the conductivity of the more expensive metals had not been determined, although relative values had been found by Wiedemann and Franz. I am very much indebted to Messrs. Johnson, Matthey, and Co. for their great kindness in preparing and lending to me wires of gold, platinum, silver, and other pure metals, of 2mm. diameter, and of such a length as to enable me to measure without difficulty both the thermal and electrical conductivities.

Unfortunately, I cannot find a record of the value obtained for the electrical conductivity of the gold wire, and it has been returned some time ago. As, however, Messrs. Johnson, Matthey, and Co. stated when sending it that it was as pure as could be made, it will perhaps be sufficient for me to use the value that has already been found for the electrical conductivity of gold as determined by other experimenters.

The curves for the calculation of the conductivity of silver wire are shown in Diagram II. The values for the different lengths are given below.

Silver Wire.

Length.	Thermal conductivity in C.G.S. units between 15deg. C. and 98deg. C.
7·86	·956
6·59	·960
6·59	·963
5·61	·973

It will be observed that the second and third values, although for the same length, differ by about $\frac{1}{3}$ per cent. They are both given, however, as they agree within the limits of observational errors. The mean of these values is ·9628.

As the curves for gold and platinum are very similar to those for copper and silver, it may be enough to give the values obtained for their conductivities.

Gold Wire (not annealed). Diameter ·202cm.

Thermal conductivity in C.G.S. unit.	Electrical resistance as determined by Dr. Matthiessen.
·7464	2188

Comparing these values with those for Messrs. Glover's copper, which was found to be ·959, we find that the thermal conductivity of gold is 78 per cent., and the electrical conductivity 81·6 per cent. that of copper.

Platinum Wire (not annealed). Diameter = ·202cm.

Thermal conductivity.	Electrical resistance.
·1861	9180

Here the thermal and electrical conductivities are each 19 per cent. of the conductivity of copper.

The gold, platinum, and silver were afterwards carefully annealed by Messrs. Johnson, Matthey, and Co., and the conductivities again determined. In each of the cases the alteration due to annealing was less than 1 per cent. both in electrical and thermal conductivity.

The results for the different metals are therefore:

Mean Conductivity between Temperatures 10deg. C. and 97deg. C.

			Diameter. Millimetres.
Copper—Specimen	1	·9594	2·00
	2	·8884	2·11
	3	·8612	3·09
Very impure	4	·3497	2·04
	5	·3198	2·04
Silver		·9628	2·02
Gold		·7464	2·00
Platinum		·1861	2·00

It is intended to use other liquids than boiling water to heat one end of the wire, and in this way test the alteration of conductivity with temperature. Up to the present time no alloys have been tested, but it is intended that tests should be made of some, such as platinoid and German silver; also iron, as pure as possible, might be tested. Instead of boiling water, steam was used for some time in this investigation, and was in some respects found to be more convenient. Fig. 7 is a sketch showing a section through the middle of the apparatus. The steam is generated in the vessel, W, passes along the upper tube, T, in the direction of the arrows, and blows directly on the end of the wire, afterwards passing out through the outside copper tube, P, and escaping by the outlet, B. The thermometer, D, indicates the temperature of the steam just when it strikes the wire. It will be seen that the outer tube with the steam in it serves as a steam-jacket, and thus keeps the steam in the inner tube, T, at a high temperature. The sloping bottom, where the wire is fixed at A, is so

Digitized by Google

made to prevent water accumulating there. To ensure that as much steam as will supply all the heat that the copper can take up is impinging at A, it is only necessary to arrange that the steam emerges at B as steam. The outside tube need not be more than 4cm. diameter, and may be round, but the part where the wire is soldered in must be thickened, and made as shown in the sketch, so that there may be no risk of water gathering above the wire. The length of the tube need not exceed 15cm. This allows sufficient length for the tube to be inserted into the screen, which prevents the heat of the lamp from altering the temperature of the ball. The diameter of the inside tube may be 1·5cm. With this apparatus the most satisfactory results were obtained.

When a metal is tested for the first time, it will be advisable to find its approximate thermal conductivity by comparing its electrical conductivity with copper. This will give an idea as to which calorimeter ball to use, and

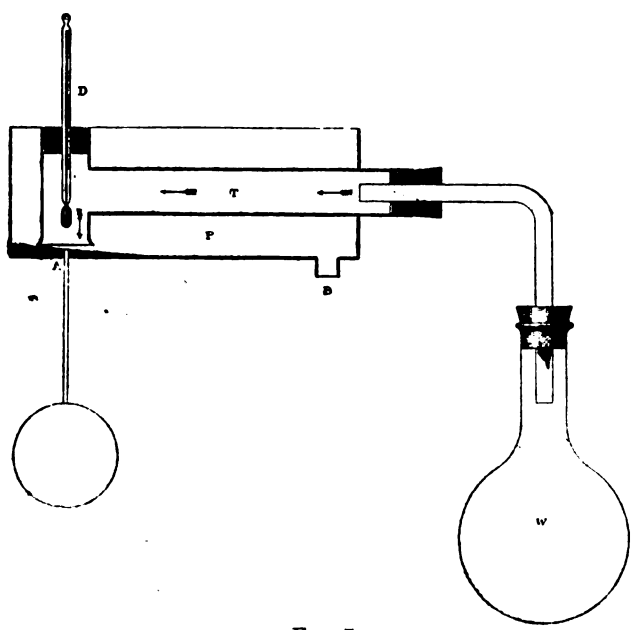

FIG. 7.

what length of wire will give a convenient rise of temperature per minute. A test is then almost as simple as for electrical conductivity.

THE THEORY OF ALTERNATING CURRENTS.—VII.

BY A.INST.E.E.

§ 21. **Alternating-Current Power.**—It is well known that the resistance of conductors dissipates energy, and that when a current of electricity flows through a conductor it can only do so at the expense of electrical energy, and the *rate* at which electrical energy is developed or dissipated is defined as electrical *power* or *activity*. When energy is utilised, *power* is the *rate* at which the E.M.F. does work, and we shall find in dealing with alternating-current power that once more we have to modify the general expression as stated for continuous currents. To determine the electrical power absorbed or developed in continuous-current circuits, we simply take the product and pressure of the amperage—that is

$$\text{power} = \text{pressure} \times \text{amperage} \quad . \quad . \quad (1)$$

or, $\quad W \text{ (watts)} = E \text{ (volts)} \times C \text{ amperes.}$

With alternating currents, however, the case is not quite so simple. As we have seen, the current and the E.M.F. pulsate at a rapid rate according to a periodic law, and it is evident that the power absorbed at one instant is not the same as that of the next; in other words, the rate of doing work varies from instant to instant. When induction is present in the circuit, the current, as we have seen, lags behind the E.M.F., and we shall find presently that the angle of lag is a most important factor as regards alternating-current power. To simplify matters, we shall state the expressions for alternating-current power in terms similar to those used in equation (1)—thus,

$$\text{alternating-current power} = \text{pressure} \times \text{amperage} \times K \quad (2)$$

in which K is a constant known as the *power factor*. The magnitude of the power factor varies according as we express the pressure and amperage in terms of the maximum or virtual values, and also whether the circuit under consideration is inductive or not. There are, therefore, two main cases to consider—*i.e.*, the determinations of the value of K for (1) non-inductive circuits and (2) inductive circuits.

§ 22. **Non-Inductive Circuits.**—In Fig. 17 is given the E.M.F. curve for a non-inductive circuit, together with the corresponding current curve. This may be considered as an example of a circuit consisting only of incandescent lamps, and it is evident from the conditions of the problem that

(1) There is no angle of lag; that is, the current curve is in phase with the E.M.F. curve.

(2) The ratios of the various lengths of the ordinates for the E.M.F. curve to the corresponding lengths of the ordinates for the current curve are numerically equal to the resistance of the circuit.

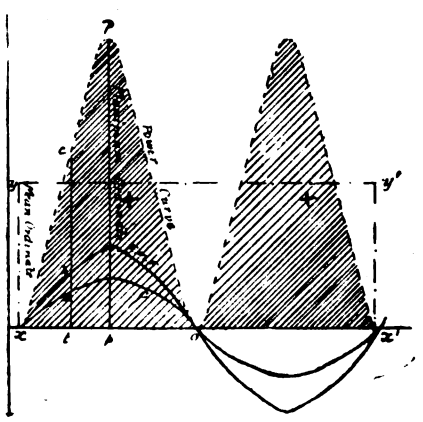

FIG. 17.

These curves give us the instantaneous values of the E.M.F. and the current for a complete period, and by multiplying together the two coincident ordinates for each division along the axis we get a series of values for the power corresponding to the instant denoted by the divisions. Thus, by multiplying the ordinate $t\,b$ by the ordinate $t\,a$, the values of the E.M.F. and the current at the instant denoted by the time t, we obtain the instantaneous value of the power at that particular point of the cycle, and by continuing this process we get a third curve by plotting the successive values of the products. This is shown as a dotted line, which with the axis encloses the shaded portion. Such a curve is designated the *power curve*, and it represents graphically the variation in the rate of dissipation of electrical energy from instant to instant.

It will be noticed that whilst the E.M.F. and current curves are below the axis, $x\,x^1$, for the second half of the period, as their directions are then negative, the corresponding power curve is placed above $x\,x^1$. The reason for this is plain. During the first half of the period the power curve is obtained by taking the product of two positive quantities, whilst in the latter half we have to multiply together two negative quantities, which, as is well known, gives a positive quantity. This result expresses a physical fact—*i.e.*, that such a circuit is always absorbing power. It is also important to notice that the sum of the areas enclosed by the power curves and the axis represents the total amount of work done during one period, since the portions shaded are, in area, equal to the product of the power and the time of one period. It will also be noticed that the power curves are perfectly symmetrical, and it can easily be proved that the sum of the two areas enclosed is equal to the area of the rectangle $x\,y$, y^1x^1, the height $x\,y$ or x^1y^1 being half the length of the maximum ordinate of the power curve.

Digitized by Google

Since the maximum ordinate $P\,p = E_{max} \times C_{max}$

$$\therefore x\,y = \tfrac{1}{2}\,P\,p = \tfrac{1}{2} \times E_{max} \times C_{max};$$

but work done in one period = area of rectangle $x\,y\,y^1x^1$

$$= x\,y \times x\,x^1 = \tfrac{1}{2}P\,p \times x\,x^1$$

$$= (\tfrac{1}{2} \times E_{max} \times C_{max}) \times x\,x^1$$

and power is rate of doing work

$$= \frac{\text{work done}}{\text{time taken}} = \frac{(\tfrac{1}{2} \times E_{max} \times C_{max}) \times x x^1}{x\,x^1}$$

or, $$\text{mean power} = \tfrac{1}{2} \times E_{max} \times C_{max} \quad . \quad . \quad (3)$$

This expression corresponds to equation (2), and $K = \frac{1}{2}$; and we see that when the maximum values of the E.M.F. and the current are stated with non-inductive circuits, the rate of the development or dissipation of electrical energy is given by the product of the maximum values multiplied by $\frac{1}{2}$.

Again, since $\frac{1}{2} \times E_{max} \times C_{max} = \frac{E_{max}}{\sqrt{2}} \times \frac{C_{max}}{\sqrt{2}}$,

$$\therefore \text{ mean power} = \frac{E_{max}}{\sqrt{2}} \times \frac{C_{max}}{\sqrt{2}} = E_{virt} \times C_{virt} \quad (4)$$

$$= (\sqrt{\text{mean square}}\ \text{volts}) \times (\sqrt{\text{mean square}}\ \text{amperes}).$$

In this form we see that the *power factor*, or K = 1; and it is evident that to get the value of the mean power of a non-inductive circuit, it is sufficient to take the product of the $\sqrt{\text{mean square}}$ values as given by a Cardew voltmeter in the one case and a Siemens dynamometer, say, in the other. Thus, the process of determining the watts expended in lighting an incandescent lamp is the same for alternating currents as for continuous currents, since the power factor in each case is unity, only suitable instruments must be used.

§ 23. **Inductive Circuits.**—When a circuit contains inductance as well as resistance the determination of the mean power is not quite so simple as the one just considered. The fact that the current lags behind the E.M.F. is well known, and it is evident that the product of the $\sqrt{\text{mean square}}$ values will not give the value of the mean power, since the $\sqrt{\text{mean square}}$ value of the pressure ordinate is not coincident with the $\sqrt{\text{mean square}}$ value of the current. The problem under consideration is given in Fig. 18,

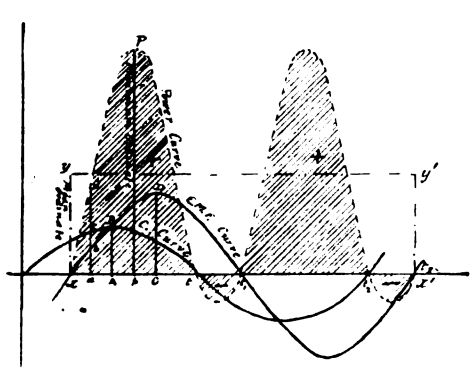

Fig. 18.

and for the purpose of comparison the magnitudes of the E.M.F. and the current are the same as in the previous case, and it will be noticed that the current is retarded behind the E.M.F. 45deg.

As in the previous case the *power curve* is plotted from the series of the instantaneous values of the power for a large number of points during a period, obtained by multiplying together the lengths of the corresponding ordinates; thus the height of the ordinate $a\ d$ is equal to the product of the heights of the ordinates $a\ b$ and $a\ c$. It is important to notice in this case that the power curve is wavy, and includes two portions below the axis $x\,x_1$. These are marked negative, since for the portions of the period indicated by the lengths, $t\,t_1$ and $t_2\,t_3$, on the axis, one of the factors—the E.M.F.—is negative in direction, whilst the current is still positive. The meaning of this is that the sum of the two areas below the axis must be deducted from the sum of the areas above the axis to give the total amount of work done during the period, from which it is plain that the height, $x\,y$, of the rectangle, $x\,y$, $x'\,y'$, will not be $\frac{1}{2}\,P\,p$, if it is to give an area equal to the amount of work actually done during the period. It can, however, be easily proved that $x\,y$ is equal to half the product of A B and C D—the maximum values of the E.M.F. and current—multiplied by the cosine of the angle of lag. That is,

$$x\,y = \tfrac{1}{2} \times A\,B \times C\,D \times \cos\theta = \tfrac{1}{2} \times E_{max} \times C_{max} \times \cos\theta;$$

where θ = is the difference of phase, or angle of lag. Since $x\,x^1$ is time, and the area $x\,y$, $y'\,x'$ measures work, therefore $x\,y$ measures *power*, or the rate of doing work;

$$\therefore \text{ mean power} = \tfrac{1}{2} \times E_{max} \times C_{max} \times \cos\theta \quad . \quad (5)$$

and the *power factor* for an inductive circuit, when the maximum values are given, is $K = \frac{1}{2}\cos\theta$.

$$\text{But } \tfrac{1}{2} \times E_{max} \times C_{max} \times \cos\theta = \frac{E_{max}}{\sqrt{2}} \times \frac{C_{max}}{\sqrt{2}} \times \cos\theta$$

$$= E_{virt} \times C_{virt} \times \cos\theta$$

$$\therefore \text{ mean power} = E_{virt} \times C_{virt} \times \cos\theta \quad (6)$$

from which we see that K, the power factor, is equal to the cosine of the angle of lag. But the cosine of an angle varies between unity and zero—that is, K has for its limiting values 1 and 0. The former is the case of the non-inductive circuit of § 22, whilst the other limit is reached when the angle of lag is 90deg. Such a case is represented by Fig. 19, which will be understood without further explanation, it being noticed that the total area is zero, from which it is evident that the rate of doing work is zero.

Between these two limiting values the magnitude of K will be a fraction, showing that the power as given by equation (6), which are termed *true watts*, is less than the product of the $\sqrt{\text{mean square}}$ volts and the $\sqrt{\text{mean square}}$ amperes, which are termed the *apparent watts*. The ratio between these two quantities, or $\frac{\textit{true watts}}{\textit{apparent watts}}$, is termed the *power factor*, which we have represented by K throughout this paper.

At this point it will be interesting and instructive to notice an example which has an important application in

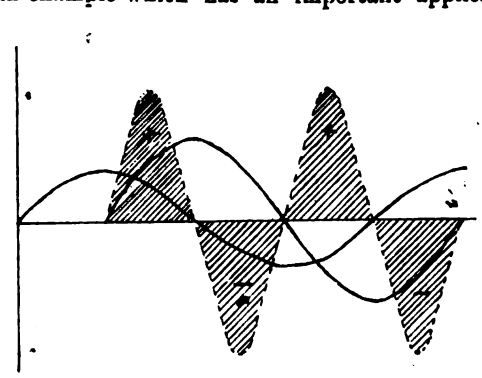

Fig. 19.

practice. Most meters used for recording Board of Trade units supplied to a circuit simply measure the ampere-hours, and assuming that the pressure between the mains is kept constant, the meters may be calibrated to record the expenditure of energy. But it is plain that a circuit may contain (1) resistance only or (2) resistance combined with inductance, and still the same current to flow under the same pressure, in which cases a meter will indicate the same consumption of energy in each case, whilst from equations (4) and (6) it is evident that the actual amount of energy is different in the two cases. This means that a consumer would be paying for more units than he has received, according to the readings of the meter.

We shall collect the various expressions for power which have been determined above, so that we may see at a glance the variations in the value of the power factor, K.

For continuous currents:

$$\text{Power} = C \times E.$$

For alternating currents:

$$\text{Mean power} = \text{pressure} \times \text{amperage} \times K;$$

$$\left.\begin{aligned} &= \tfrac{1}{2} \times E_{max} \times C_{max} \\ &= E_{virt} \times C_{virt} \end{aligned}\right\} \text{non-inductive circuits;}$$

$$\left.\begin{aligned} &= \tfrac{1}{2} \times E_{max} \times C_{max} \\ &= E_{virt} \times C_{virt} \times \cos\theta \end{aligned}\right\} \text{inductive circuits.}$$

THE TESTING OF ALTERNATING-CURRENT DYNAMOS.*

BY H. BEHN-ESCHENBURG.

As is well known, that quantity which most surely determines the value and efficiency of an alternating-current dynamo is the fall of potential—*i.e.*, the difference in the potentials at the terminals of the dynamo, 1deg., when no current flows through the armature, and 2deg., when the armature windings generate a current which has a definite difference of phase with the terminal potential, the revolutions and the current in the magnetising field being constant in both cases. In other words, the fall of potential is the difference in the potentials (with constant excitation and revolutions) at no load and at a certain definite load. This fall of potential is determined essentially 1deg., by the reaction of the "current-carrying" armature windings on themselves; 2deg., by the copper resistance of these windings; and 3deg., by the reaction of the Foucault currents induced by the armature currents, principally in the massive iron field magnets.

These determining factors of the fall of potential may be represented as E.M.F.'s which, in definite phase, combine with the E.M.F. of the dynamo to form the resultant terminal potential.

We thus obtain three E.M.F.'s in the armature windings, proportional to the currents in the armature, which we place in a polar diagram, Fig. 1, according to their effective values and their phases—*i.e.*, their directions—and designate by e_1, e_2, e_3.

In the same diagram we let I represent the armature current (*i.e.*, the load current of the dynamo); E, the E.M.F. of the dynamo, which is equal to the terminal potential difference at no load; and E_1, the terminal potential difference when loaded. The direction of the different quantities is determined by the angle of the phase difference which they have relatively to the current, I. There will now naturally be a phase difference of $\frac{\pi}{2}$ between the E.M.F., e, of the self-induction and the current; and between the E.M.F.'s e_1 and e_3 and that of the current a phase difference of 0. We assume, further, that for the chosen load of the dynamo the phase difference between the terminal potential difference and the current is ϕ, where ϕ is defined by making the delivery in watts of the dynamo $W = E_1 I \cos\phi$.

For lighting distribution with transformers, ϕ is about 10deg. and cos ϕ practically equal to 1; and for power distribution with non-synchronous motors ϕ may be taken as about 35deg. and cos ϕ about 0·85. The fall of potential of the dynamo, taken from the diagram, equals $E - E_1$.

For synchronous motors the same diagram is to be employed when the E.M.F. of the synchronous motor is greater than the terminal potential difference; if, however, $E = E_1$, e is to be drawn in the opposite direction.

The resultant, e of the three E.M.F.'s, e_1, e_2, and e_3, in a phase α relative to I, represents the total counter E.M.F. of the "current-carrying" armature. By this E.M.F. e, and the current I, and apparent resistance of the armature windings is defined as

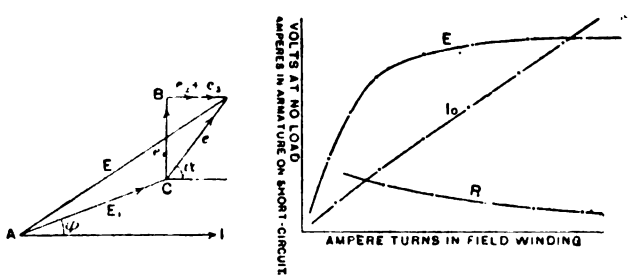
$$R = \frac{e}{I}.$$

A chief problem in the testing of alternating-current dynamos is to ascertain and calculate in advance this resistance, R and e, as when they are known all quantities important for operating may be taken directly from the diagram, Fig. 1.

For this purpose I have for some time taken the following course, which I most heartily recommend to my colleagues. In the first place, there is drawn in the ordinary manner a characteristic of the E.M.F. of the dynamo when no current flows in the armature (compare Fig. 2, Curve E). The abscissæ are the number of ampere-turns of the magnetising continuous current—that is, the strength of the exciting current—and the ordinates are the induced E.M.F.'s, E, of the dynamo at a fixed number of revolutions. A second characteristic, I_0, is taken after the armature windings have been short-circuited by an ammeter across their terminals. The abscissæ are again the number of ampere-turns of the field, and the ordinates are the current strengths of the short-circuited armature in amperes (designated by I_0). This curve I_0 as a rule, differs but slightly from a straight line; with strong fields it is a little convex.

For the case of the short-circuited armature, the diagram, Fig. 1, is to be changed so that $E_1 = 0$, $E = e$, and we then immediately obtain in Fig. 3, $e = E$, and $R = \frac{E}{I_0}$ for every value of the abscissæ.

This value of R we place as ordinates in Fig. 2, and so form a third characteristic, R, of the apparent resistance for every value of the field strength.



FIGS. 1 AND 2.

For any value of the load current, I, with a fixed field excitation, $e = R I$ is given directly, and E_1, and ϕ may be calculated from the diagram. With a given field current, either E, ϕ, and I are to be assumed as given and E_1 is to be determined in advance, or E, E_1, and I are given or observed and ϕ is to be determined from them. The following formulæ result from the oblique-angled triangle, A B C, of the diagram:

$$\cos(\alpha - \phi) = \frac{E^2 - E_1^2 - e^2}{2 E_1 e};$$

$$E_1 = E - e\cos(\alpha - \phi) - \tfrac{1}{2}\frac{[e \sin(\alpha - \phi)]^2}{E}.$$

(The counter E.M.F., e, should naturally be considerably smaller than E in practical cases.)

Finally, in order to ascertain the difference of phase α between e and I_0 or I, we must observe not only the current I_0 with short-circuited armature, but also the watts consumed, $E I_0 \cos\alpha$, either directly by means of a watt-meter, or by measuring the expenditure of energy necessary to drive the short-circuited dynamo; this last may be done by observing the watts used by a continuous-current motor employed to drive the alternator. With good dynamo machines, α is greater than 80deg., and for approximate measurements may be put equal to $\frac{\pi}{2}$. This means that the copper losses and the losses through Foucault currents should be very small compared with the losses in potential. The component e_2 of the E.M.F. e is easily determined by means of resistance measurements, for if r be the armature resistance, $e_2 = I r$.

The component e_3 increases approximately with the square of the number of revolutions, and so can be separated from e_2. As a check, α can be calculated when measurements with the dynamo loaded have given observed value of E_1, E, I, and ϕ; for instance, when $\phi = 0$, or $\phi = \frac{\pi}{2}$, with wholly inductionless or purely inductive load

* From the *Electrical World* (New York).

Digitized by Google

respectively, or when ϕ is determined by means of a wattmeter.

(It is to be remarked that for small values of ϕ, for instance, with transformers, the diagram will give much more accurate determinations than a wattmeter, for from the diagrams in ϕ and from the wattmeter cos ϕ is read.)

If, as an approximation, we make $\alpha = 90$deg., the formulæ for ϕ and E will become simplified, as follows:

$$\sin \phi = \frac{E^2 - E_1^2 - e^2}{2 E_1 e};$$

$$E_1 = E - e \sin \phi - \frac{e^2 \cos^2 \phi}{2 E};$$

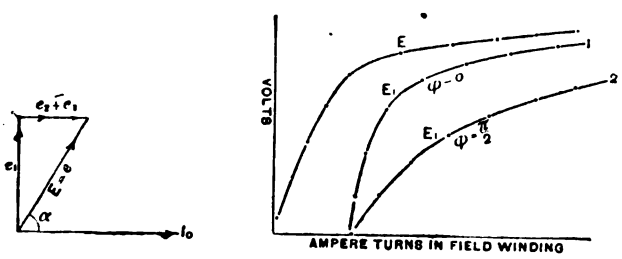
and for the limiting cases of inductionless and purely inductive load:

$$\phi = 0; \qquad E_1^2 = E^2 - e^2;$$

$$\phi = 90\text{deg.}; \quad E_1 = E - e.$$

The two characteristics, E and I_0, may be taken in a very short time with a voltmeter, a continuous-current ammeter, a speed-counter, and an alternating-current ammeter. The dynamo requires in this case only 10 to 20 per cent. of the normal power to drive it—*i.e.*, the energy loss of the loaded dynamo.

The short-circuit current, I_0, during the short time which is necessary for the observation, may be raised without



FIGS. 3 AND 4.

hesitation to two or three times the normal current. When taking the short-circuit curve, I_0, the number of revolutions are of small importance, for with a fixed field magnetisation the short-circuit current will naturally remain constant at all speeds.

In the curve diagram, Fig. 4, are drawn the special characteristic curves of the terminal potential, E_1, calculated from Figs. 1 and 2, which correspond to the dynamo load when carrying a current I in the two limiting cases $\phi = 0$ and $\phi = 90$deg., for all field excitations and $\alpha = \frac{\pi}{2}$. These are the curves 1 and 2, between which, for all possible value of ϕ, must be the terminal potentials of the dynamo with the current I.

Besides the quantity, R, determining the efficiency of the dynamos, this method gives a clear picture of the leakage conditions of the machine. The ampere-turns of the "current-carrying" armature windings must act inductively on the same magnetic circuit; the lines of force which are induced by one of these windings without cutting the turns of the other, are designated as scattered lines.

We will assume that $100 \times S_1$ per cent. of the total lines induced by the field winding and $100 \times S_2$ per cent. of the total lines of the armature winding are scattered, and so lost for useful inductive working.

Let the number of turns of the field be w_1, and of the armature w_2, in which both numbers are to be reduced to the same magnetic circuit. This reduction is easily accomplished by the help of a systematic drawing, in which the magnetic circuit—that is, the closed courses of the magnetic lines of force in the dynamo—are drawn as linear conducting circuits, in analogy to the diagram for branching electric currents, and the ampere-turns of the armature and the field, at the places where the windings are cut by the circuit of the lines of force, are designated as magnetomotive forces, analogously to E.M.F.'s. The number of lines of force, in analogy to a current strength, is calculated for every part of the circuit according to Kirchhoff's rules for divided currents. For the short-circuit, equality must obtain between the magnetomotive forces of the armature current and the field current as far as the ampere-turns which occasion the scattered induction and those which induce the E.M.F.'s e_2 and e_3. These equal ones are the magnetomotive forces which induce the E.M.F.'s E and e_1.

We thus obtain the important condition:

$$(1 - S_1)\, i_0 w_1 = \frac{1{\cdot}4\,(1 + S_2)\, I_0 w_2}{\sin \alpha},$$

in which i_0 is the continuous field current, and the factor 1·4 in the right member the amplitude of the mean value of I_0.

If the field system possess a single magnetising coil, w_1, as is easily seen, must be multiplied by half the number of poles; and if the armature system consist of N phase divisions, w_2, in the right-hand member, is to be multiplied by $\frac{N}{2}$, and w_2 signifies the number of turns of one phase division.

From this equation, which besides the number of turns presupposes only the observation of the Curve I_0, we obtain for every excitation of field the value of the loss of potential in per cent.—that is, the value of the ratio of the counter E.M.F. e to the E.M.F. E_1 of the dynamo with a load current I:

$$\frac{e}{E} = \frac{I}{I}; \text{ or, also, } \frac{e}{E} = \frac{I w_2}{i_0 w_1} \cdot \frac{1{\cdot}4\,(1 + S_2)}{(1 - S_1) \sin \alpha}.$$

That is to say, e has the same ratio to E as the load current has to the short-circuit current, with constant excitation; or, as the number of ampere-turns of the armature to those of the field, multiplied by a factor approximately equal to 1·4. This factor is:

$$\frac{1{\cdot}4\,(1 + S_2)}{(1 - S_1) \sin \alpha} = \frac{i_0 w_1}{I_0 w_2}.$$

The leakage value, S, is, on the other hand, easy to calculate when the principal dimensions are known, so that the preceding formula will give the value of S_2, which is difficult to calculate. The total magnetic resistance, ρ, of the magnetic circuit of the field and armature winding is calculated in the usual manner from the individual resistances of the air-gaps and the iron parts at the chosen saturations.

If we designate the total number of lines induced by the ampere-turns of the field by $\mathfrak{B}$, and the number of alternations of the dynamo by n, the well-known equations obtain:

$$E = \frac{\mathfrak{B} \cdot w_2 \cdot 2\pi n}{1{\cdot}4 \times 10^8} \frac{4\pi}{10} i_0 w_1 = \mathfrak{B} \rho\,(1 + S_1).$$

Also,
$$1 + S_1 = \frac{5{\cdot}6\, i_0 w_1 w_2 n}{E \rho\, 10^8}.$$

On the other hand, in the case of the short-circuit:

$$I_0 R = E, \text{ and } R = \frac{8 w_2^2 n\,(1 + S_2)}{\rho\,(1 + S_1)\,(1 - S_1) \sin \alpha\, 10^8}$$

This last equation shows us the constructive meaning of the apparent resistance, R, of the dynamo. R increases proportionally to n, and with the square of the number of turns.

By means of this sketch I believe that I have shown a very convenient method, which I have myself tested in a number of practical cases, giving direct values which make possible an exact and unobjectionable comparison and discussion of alternators. Knowing the characteristics for no load and for short-circuit, the limits of the loading of every dynamo for a prescribed terminal potential difference can be determined beforehand; that is, the values of the current strength and of the shifting of phase between the current and the terminal potential.

Annual Outing.—The employés of the Electrical Company, Limited, 122 and 124, Charing Cross-road, and the Calmon Asbestos and Rubber Works, British Agency, of the same address, together with a few guests, under the congenial leadership of their managing director, Mr. F. T. Eggers, held their second annual outing on Tuesday, the 16th inst., when a most enjoyable day was spent.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THAT "RARA AVIS"—A NEW COMPANY.

Our gaseous contemporary is sarcastic in the following manner: "At last there is news of another electric lighting company being brought before the public, and the event is of sufficient rarity to call for notice on this account. When things are very scarce—like great auk's eggs—they have a certain notoriety for this reason alone, irrespective of their intrinsic value or interest. So it is nowadays with new electric lighting companies. There was a time when these ventures were hatched out at the rate of two or three a week. But those days are gone, never to return. 'There are no eggs in last year's nests,' says the Spanish proverb. Therefore, when one hears of an announcement that the British public are again asked to put money into an electric lighting company, one wonders why the promoters are not content to do as electric lighting schemers generally have done for several years past—get their money out of the ratepayers."

We venture to think that our contemporary is seldom fair, and in this particular instance is cynically unfair. It knows that the said company or proposed company has met with no sympathy from the electrical technical Press—in fact, not only that it has met with no sympathy, but has by one electrical paper been soundly "slated." The *Journal of Gaslighting, etc.*, however, always shows an excessive eagerness where electric lighting is concerned to try to make black appear white. A red rag in front of a bull is a tamely inflammatory proceeding to the mention of electricity to the *Journal*. The former inflames the beast to a natural fury; the latter unhinges every spark of logic or argument. It seems to us that our contemporary works systematically to find bad points in electrical works, and refuses with the blindness of the man who will not see to acknowledge any good points. We are not very much concerned about how our contemporary conducts its crusade, because we conceive it has chosen the worst possible course, and every week, because of their very ostensible virulence, damns its own criticisms to all thinking men. It is perhaps unfortunate, however, that the world contains a large number of unthinking people who believe what they are told. In the hurly-burly of everyday life it is too much trouble to enquire as to the correctness of a statement, and we are often told that giving a "lie" twenty-four hours' start means impossibility in overtaking and correcting it. Now, a few plain words in connection with electrical companies may not be out of place. There exists a class of men called "company promoters," whose livelihood is derived by a due use of their brains and a thorough belief in Carlyle's view of mankind—that they are "mostly fools." Ninety-nine per cent. of the companies brought before the public are the result of company-promoters' actions—that is, so far as electricity is concerned, the action of men who have no technical knowledge whatsoever; who care nothing for the future of a company or the value of its assets; whose every care, in fact, is promotion-money, founders' shares, and Stock Exchange quotations. These men generally exploit patents, and for these

Digitized by Google

patents can obtain satisfactory sentences in reports —from those who know and those who don't know— for satisfactory payment. A class of reports of the most annoying character during the last fifteen years has come from professors. The reports are in a sense true, but from a practical point of view are about as misleading as can possibly be devised. Prof. Optimistic has a patent put before him, and pockets a large fee to give a report. He does not deem it his duty to enquire into the purpose for which the report is to be used, and from his laboratory standpoint examines into the matter. This is all very good in its way, but, like too much plum pudding, requires a corrective, and the corrective ought to be applied by the practical man, who generally, as soon as he is asked to look into the matter, says it is not worth a damn. The exploiters flood the country with selected quotations, and pocket the sovereigns as they roll in. That is good business; and, so far as we are concerned, if fools will part with their money it is not our business to sympathise with the loss. We contend that the moral to be drawn from this company-mongering is, when a likely industry is started, clever City men see their opportunity of making money and they make it. First, they must have a good solid foundation to work upon. In electrical development they had it, and they ran it for all it was worth, till electrical company-mongering stank in the nostrils of the public. Another string to the bow of the company-mongers has been the promotion and exploitation of provisional orders. The success of gas monopolies underlay this action. It was early seen that under ordinary circumstances two or more electrical companies could not run side by side in one town, and there being in those early days hesitation for municipal authorities to take the plunge, the 'mongers thought to have a good time. The measure of success in this direction was not great, hence a diminution in the initiation of these companies. With the exception of that portion of the technical Press which is run by and on the behalf of company-mongers and trade cliques, there has been no hesitation in decrying these attempts to obtain money. It may be taken for granted that the exploitation of patents and the exploitation of provisional orders hardly present any inducement to company promotion at the present time. There are a few spasmodic attempts, at longer and longer intervals, to form a company in these directions, and the attempt decried by our contemporary is one such. It will be gathered from the foregoing remarks that, so far from looking upon the laxity of such company formation as an evil, we think it is an unmixed good. Once more we say that the previous attempts to run companies were made because clever City men saw that electrical work was sound. The work is now being carried out upon better business lines than by speculative company formation. The people who want the work done are now the people who are having it done and finding the money, instead of allowing outside people to exploit schemes for the sole purpose of adding exploitation costs to required capital. There is a vast difference in having work done because experience shows you want it, as against having it done because someone else says you want it.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE FIRE AT THE SALFORD WORKS.

SIR,—As a report has appeared in the Press of a fire which occurred on last Saturday night at our works at Salford, may we avail ourselves of your columns to inform you and our many friends and customers that only one department of our business was affected, and that all work is being carried on as usual and without delay?—Yours, etc.,

W. T. GLOVER AND CO.

Westminster, S.W., July 17, 1895.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 35.)

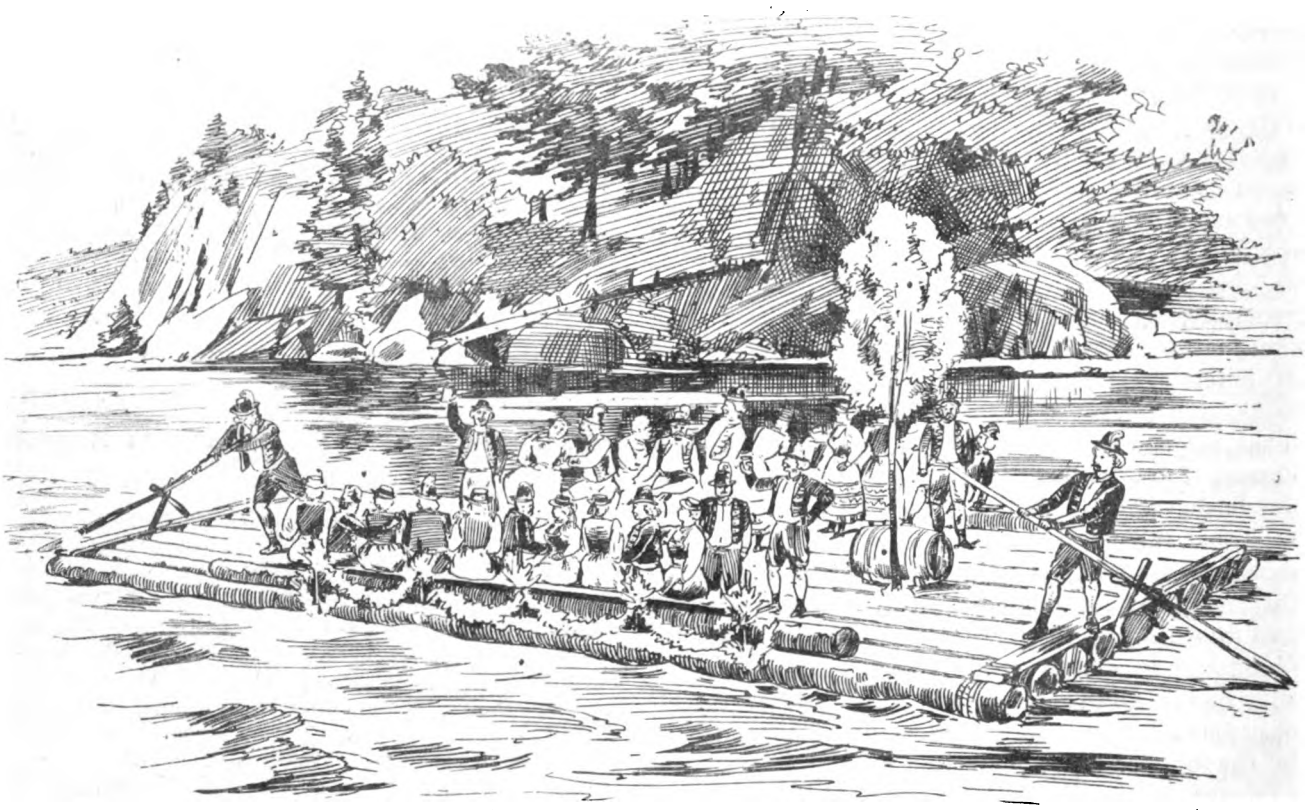
FRIDAY, JULY 5.

The afternoon meeting in the Museumssaal, Promenadestrasse, was well attended, in spite of the wetting so many members had undergone while listening to the speeches which followed the unveiling of Ohm's statue. I noted, however, that many appeared in evening dress, which showed that I was not the only one wet through. The papers read in the afternoon included one on the Munich electricity works, by Herr F. Uppenborn. The diagrams round the walls fully explained the methods of street-lighting used in the town, and the design of the generating station. The arc lamps are in most cases suspended in the centre of the street at a height of about 33ft. above the roadway. The weight of the lamp is taken by a steel wire attached to the houses at either side. A pulley in the centre of this wire carries the wire by which the lamp is hoisted into position, and which, after passing horizontally to the house at one side, is led down to a rachet wheel on the wall. The conducting wires follow the same course. The lamp in being lowered describes the arc of a circle till a position is reached from which it can be conveniently trimmed from the footpath. The many ingenious devices which Mr. Uppenborn has got out in connection with these arc lamp suspensions will be more fully described when I get the promised drawings of them. The lighting effect of the lamp so suspended is exceedingly good, as there is no shadow cast on the street. At night it is difficult to see even how the lamps are suspended until late, when every alternate lamp is extinguished. In large public squares, where this method of suspension is not required, a number of arc lamps (three to five) are placed on masts at intervals in the centre, and then single arc lights on ordinary lamp-posts are used round the outside of the open spaces to be lighted. In all cases the lamps are lowered to be trimmed. The circuits are so arranged that alternate lamps can be extinguished to economise power after the busy periods of the night are passed. The rest of the details as to the central-station voltage, etc., will be given later, after the papers have appeared in the official organ of the society.

Another interesting feature in the afternoon sitting was the paper by Dr. W. Wedding on "The Comparative Studies of the Lighting Values of Acetylene, Gas, and Electricity." The last paper of the sitting was, it appears, specially arranged for the benefit of the ladies. It was by Herr Paul Stotz on electric cooking apparatus. A large number of the lady members of the Munich meeting flocked in and waited impatiently while the scientific part of the paper was read. The principle of the construction of the apparatus on view was the employment of a thin tissue of high-resistance alloys woven in an asbestos core. The string

Digitized by Google

thus formed was coiled in spirals round the bottom of the various heating appliances. Personally, I prefer the construction of resistance in enamel, as made in England. Immediately the paper was read and the demonstration of cooking began, the ladies stormed the platform and critically examined the apparatus and the products from the various grills, etc. Sections of sausages which had been branded by the hot resistance cores were handed round. I gathered that one advantage of the beefsteaks cooked on the grill was that you could use them for chess-boards if the marks left by the resistance cores were only sufficiently numerous and rectangular. The distinctness of the marks left was never in question, but the ladies seemed to doubt that so much local heat was good.



Descending the Isar on Rafts.

At six p.m. the same evening we met again for "Fest-Mahl," commemorating the third annual meeting of the Verband Deutscher Elektrotechniker. This was held in the old "Rathhaussaal," or town hall, of Munich. The large hall in itself was most interesting from the array of carved woodwork, coats-of-arms, and flags which it contained.

Badge of Membership.

No specified seats were assigned to members who did not receive places at the chief table, but I was fortunate to receive an invitation from Mr. F. Drexler to join the Vienna party. This gentleman, who is the representative of the noted Oerlikon firm at the Austrian capital, introduced me to many of his friends who, like himself, could speak English fluently, so that I was able to gain much valuable lore in the German art of dining. The menu was a typical German one, and the toasts were taken between the courses. This method is good for digestion, though it made the dinner of seven courses spin out over three hours.

At the commencement of the dinner, memorial beer-jugs were placed to each guest. This jug, of which an illustration is given, is a production worthy of both the art and the beer of Munich. The handle of the lid is fashioned to represent the tower of the cathedral, and in the centre of the lid there is a copper electro of the badge of membership. The figure on the jug is the "München Kinder" of the legend. I enquired from my left-hand neighbour what the child of Munich did with his book, but a technical subject claimed our attention at that instant, and the legend was not forthcoming. The beer itself did not long hold out under the repeated toasts

Memento of the Verband Meeting in Munich.

Digitized by Google

and the custom of clinking glasses with everyone within walking distance. It was very amusing to a stranger to the custom like myself to see an amiable doctor-professor come smiling down the room to clink glasses and utter the mystical term "Prosit" with a group of old friends. The custom also gave me many introductions, and before leaving the room my circle of acquaintances had increased threefold. It would be a valuable addition to some of the corporation festivals, where a trot round the table between courses would do a vast amount of good. The speeches were numerous but short and to the point, and after the various toasts the "Hochs" would have done credit to the breaking-up day of a public school.

Amongst those to whom I was introduced was Dr. Hermann Aron, the originator of the meter of that name. At this dinner the lady members appeared in full force, and throughout the whole of the meetings shared the enjoyment provided by the Munich committee.

The toast list was as follows: "The Kaiser and the Prince Regent of Bavaria," proposed by the Chairman, Prof. Dr. A. Slaby; "München," by Prof. Budde; "Electrical Engineers," by Bürgermeister Borscht; "The Verband," by Geheimrath v. Pettenkofer; "Herr v. Pettenkofer," by Herr Oskar von Miller; "Sculptors of the Ohm Statue—v. Ruemann and Thiersch," by Prof. Sonke; "The Ladies," by Herr F. Ross.

Saturday, July 6.

The papers to be read this morning were some of the most important of the interesting collection provided for the Munich gathering. The previous facilities for getting through the business were not considered sufficient, so an additional room was provided at the further end of a long gallery. The *modus operandi* then was as follows: Mr. G. Hummel read his paper on "Electric Meters" in the large room, and then, while the interested members were examining the models and diagrams, the others passed through into the other room to hear a paper by Dr. F. Ross on the Dubiau boiler. The arrangement was, in electrical terms, a two-phase system with currents at right angles. The one thus reached its maximum value while the other was at zero. There was, however, a conductor joining the two circuits whose impedance tended to perceptibly reduce the currents in either circuit. The conductor, or gallery, in question consisted of a combination of a small resistance and a large amount of self and mutual induction, which reacted on the capacity of the members. In other words, the refreshments temptingly displayed in the gallery prevented many members from reaching their destination when they were passing from one room to the other.

The paper on the Dubiau boiler was listened to with great attention, and by the kindness of the author I shall shortly be able to give the particulars and the illustration. The next item was by Dr. G. Roessler, of Berlin, on the effects of the wave form of alternating currents on the efficiency of a transformer. The conclusion arrived at by the author, from practical testing confirmed by mathematical reasoning, was that the iron loss in transformers is much less when currents with curves having irregular and peaked forms are used than with regular-shaped curves. The experiments were a continuation of similar investigations on the effect of the curves on the light-giving properties of an arc by Dr. Wedding and the same author; and it is curious to notice that what is bad for arc lamps is good for transformers, and *vice versâ*. There was not time at the meeting to go deeply into the reasoning and the methods of making the test, but I am much surprised at the conclusions arrived at. One naturally would expect the peaked curve to give highest maximum inductions, and hence greatest loss.

After a few more contributions to our scientific knowledge the indoor business of the session closed, and we commenced the excursion to view different works. By the aid of the electric tramway we proceeded to a railway station on the outskirts of the town. One noticeable feature in the Munich tram system is that most of the cars are open, with the exception of an awning, the seats being placed transversely. The trams are not stopped except at the principal street corners; at other places the passengers, including ladies, leave and join the car while it is in motion. The electric cars are not as yet running except on one or two sections, and the increased speeds of these may prevent open cars being so much employed. From the rail we proceeded to an intermediate station on our way to the Isar works and partook of an excellent lunch at a restaurant in the woods. Some worthy youth kept firing off a small cannon in our honour at irregular intervals. The effect on one's nerves was not pleasant, and the wish that the gun might burst was freely expressed. After lunch, we went on by special train to a station on the banks above the Isar works and walked down to them through most lovely woods. I leave the description of the works themselves till last, and will only chronicle my ideas. Firstly, the River Isar is quite unlike any river we have in England. It is always in a great hurry to get to the Danube, and the average speed of its water is at least eight miles an hour. Again, the quantity of water in the main channel is not perceptibly affected by the power works as far as I could see, and at the dam we visited on Saturday the quantity passing over the weir was enormously greater than that going into the head race. Locks are not used, but broad water shoots are left for the descent of rafts, etc. We visitors, after having the waterworks described, proceeded to the power-house. The general appearance of the interior of this does great credit to all concerned. Mr. Oskar von Miller explained to us the electrical details, though the construction of the large three-phase alternators required no explanation to me, as one was standing and could be freely examined. After enjoying a cup of electrically-boiled coffee, we proceeded to get aboard four timber rafts which were waiting in the tailrace to take us down the river. The rafts are beyond description in a paper debarred from the use of coloured illustrations. Their construction was simple: a number of rough tree-trunks, about 40ft. long, were fastened together at either end, and the space of 10ft. at each end was taken up for the steersmen. In the centre two logs were placed, about 2ft. above the others, at either side, and boards on these formed seats for our party. A silver-beech tree in the front marked the refreshment department, where the liberality of the Isar works directors was dispensed in the shape of "München bier" and sandwiches. The sides were decorated with green fir boughs. In the second raft the band was placed, so that at first we glided slowly down the tailrace enjoying sweet music. When, however, the main stream was reached the rafts assumed open order, and we, as the last raft, lost sight of those in front. The pace was most exhilarating, but when we approached the next weir I noticed that standing room on the seats was at a great premium. Our leading steersman, after assuring himself that our bark was going straight for the shoot, fastened up his large sweep, and came back into the body of the raft. We entered the shoot, and for an instant glided swiftly and smoothly down the rapid incline. Then came the broken water at the foot of the shoot. At the first plunge the wave surged quite 3ft. over the bow ends of the logs, and at the front of the centre portion water came up about ankle deep. Of course there was a good deal of spray, and those folks on the seats did not by any means escape this secondary effect. We had two such experiences on our way down, both of which afforded much amusement. I understand that the paternal police superintendent forbade the raft trip when first organised, and that the local committee only carried their wish by agreeing to insure every passenger for the modest sum of 50,000 marks—*i.e.*, £2,500—so that they should at least be worth drowning. We disembarked at Ludwigsbrucke to view the distributing system of the company. The following is a brief description.

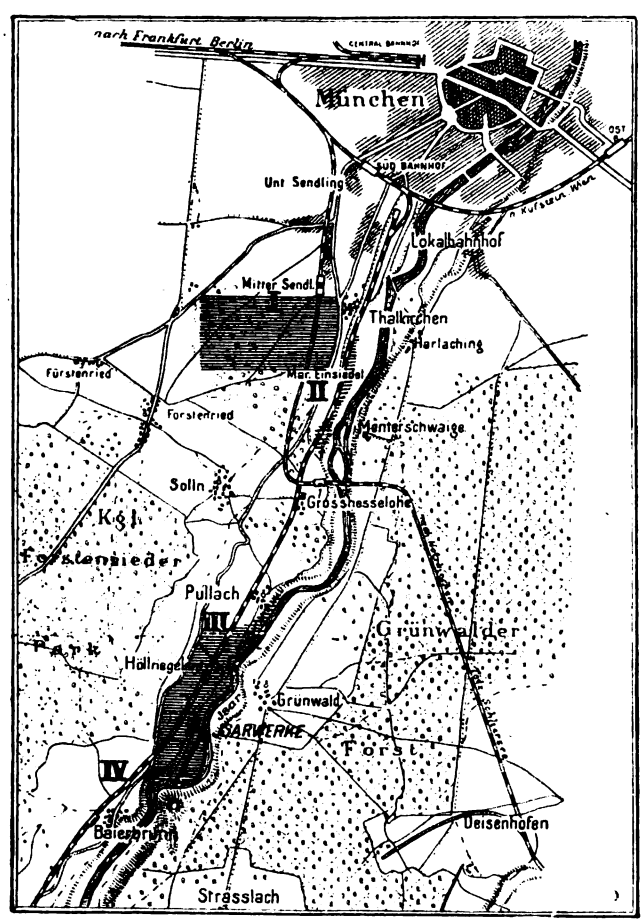
The Isar Works.

It was towards the end of the eighties that Mr. Heilmann, of Munich, conceived the idea of utilising for industrial purposes the water power of the Isar, a tributary of the Danube. The most suitable spot for the undertaking was found to be the narrow valley near the old lime furnaces in aptly-named Höllriegelsgereuth. It was also found to be necessary to secure the rights over the whole of the stream from Baierbruun to Grosshesselohe (see map),

Digitized by Google

which represents, with an average depth of water, 6,000 h.p., and in winter, with the water low, 4,000 h.p. To utilise the water power it was essential to construct at Höllriegelsgereuth a massive weir in order to collect the water and conduct it to a channel on the left bank of the Isar. The concession for the works was given in 1891, and they were completed within four years.

On the left bank of the river the dam, 110 yards long, is connected with the sluices—viz., two concrete sluices each 10ft. wide inside, a float-passage 23ft. wide, and six canal sluices of a total inside width of 85ft. The canal, which has a sill width of 85ft. (3ft. wider than the Suez Canal, and 12ft. wider than the Baltic Canal), a smooth-water width of 109ft., and a depth of water of 6ft., is capable of passing 1,940 cubic feet of water per second. At high water the depth can be increased to 8·5ft., and the quantity to 2,300 cubic feet per second. At a distance of 880 yards below the weir is placed the first plant, with a capacity of 2,000 h.p. This plant consists of the turbine-house, a tailrace, and a float-passage. The whole of the



Plan showing the Isar Works and surrounding country.
I. Mittersendling Station. III. Hollriegelsgereuth Station.
II. Maria Einsiedl Station. IV. Baierbrunn Station.

foundations and waterworks are built with Portland cement on piles. The canal and weir works for utilising the total 6,000 h.p. from the Isar have now been completed, so that only the necessary buildings, etc., for the second and third plants are required. The whole of the concrete work was carried out by Messrs. Widmann and Telorac, of Kempten.

The present turbine-house is to be fitted with four Jonval 500-h.p. turbines, driving the same number of alternators. The arrangements made for keeping the ice from the weir, carrying it away from the first plant, and for preventing the turbines from freezing, have already proved satisfactory, despite the exceptionally severe winter. At present two turbines are in place and working, but the others can be put in position in a very short time and without interrupting operations. The turbines in the machinery building are geared by mortice bevel gearing to three-phase rotary-current dynamos made by Brown and Boveri. There is also on the same shaft an ordinary continuous-current dynamo for excitation, which delivers current by means of sliding contacts to the windings of the star-shaped magnets which are fixed on the flywheel. The armature core and coils are enclosed in a rigid iron frame, which is capable of rotation round the same axis as the magnets to bring any desired coils to a convenient position for examination. Contact is made automatically when the frame is barred round into its original position. This is done by means of knife contacts on the frame, which engage into jaws attached to the concrete in the gap of the foundation.

The three-phase currents, generated at 5,000 volts by the dynamos, are conveyed to the switchboard, and there can be connected to the mains going to the distributing stations. The switchboard is designed with a view to the safety of the operator, the 5,000-volt switches being placed out of reach and operated by means of long wooden handles. Mr. Oskar von Miller designed the electric plant and superintended its erection.

The energy obtained is used for power, lighting, and heating purposes, and is conveyed to the individual consumers by bare copper conductors, 0·300in. diameter, carried on high poles. In the transmission, to a distance of 5⅝ English miles, of a current produced by 1,000 h.p. the loss only amounts to 9 per cent. The current is transformed down from 5,000 volts to 100 volts before it is supplied to consumers.

The water and electricity works at Höllriegelsgereuth came last autumn into the possession of a limited company, with the title "Isarwerke," which supplies electric energy for power and lighting purposes at very cheap rates. In Thalkirchen alone 2,100 16-c.p. lamps are run from the Isar works, and 400 more are being fitted. As to the supply of power, electric motors of 140 aggregate horse-power are so far in use. Among the firms in Thalkirchen availing themselves of the new facilities for obtaining motive force the following trades are represented: joiners, venetian-blind makers, engineers, saw-mills, corrugated-iron makers and galvanisers, laundries, and brewers. Various other industrial establishments which are either projected or in course of construction at Mittersendling will also derive their power from the Isar works.

In the offices of the manager, Herr Drentwett, a collection of electrical novelties is shown, as well as the practical application of electricity to household requirements.

THE LENOX AVENUE CONDUIT RAILWAY.

The conduit of this railway, which was designed and manufactured by the General Electric Company, has now been put into operation, and is running very successfully. The engravings presented herewith will give an excellent idea of the construction employed.

In installing the line, the street railway company proceeded upon the most conservative lines, and determined to reduce the consequences of failure to the minimum of damage which would inevitably arise from any stoppage in the service. The plan, therefore, contemplated the construction of the line as if for a cable road, in order that, should the electrical system prove unsuccessful, the electrical portion could be taken out, and the cables and pulleys of a regular cable system introduced into the conduit, without loss of time, and at comparatively small expense.

The Lenox-avenue line is a double-track road, starting at the car-house at 146th-street, and running directly south to 116th-street, into which it runs, and proceeds as far west as Manhattan-avenue. It turns here, and runs as far south as 108th-street, along which it is carried to the junction of that street and Columbus-avenue. The district which this line will serve is at present somewhat sparsely settled, but the facilities of transit which it will afford will probably result in the rapid development of that region.

The power house is a temporary frame structure, with a sheathing of corrugated sheet iron, located on 146th-street, a few yards west of Lenox-avenue. Steam is supplied from two Babcock and Wilcox water-tube boilers, arranged in one battery. Each has a rated capacity of 250 h.p., furnishing steam at 120lb. The engines, two in number, are horizontal, cross-compound Allis-Corliss machines, which, during the experimenting trips, will run non-condensing. All the steam-piping is placed beneath the

Digitized by Google

floor of the engine-room. To each of the engines is coupled a General Electric 400-kilowatt generator, of standard construction, but wound for 350 volts, instead of 500 volts, as is the usual practice in railway work. This machine is placed between the high and low pressure sides of the engines.

From the generators the cables run beneath the switchboard to a subway under the sidewalk on 146th-street, extending as far as Lenox-avenue, where they are introduced into the 5in. iron pipes running parallel with the conduit. For the present the line will be operated directly from the new power-house, but the feed wires will probably be placed in the pipes and will be tapped into the conductor at the necessary points.

The construction of the underground contact system is simplicity itself. The plough suspended from the crossbar of the car truck passes through the slot in the centre of the track and presses against the flat surfaces of two iron conductors running the entire length of the conduit. These conductors are placed each 3in. on each side away from the centre of the slot to avoid deleterious

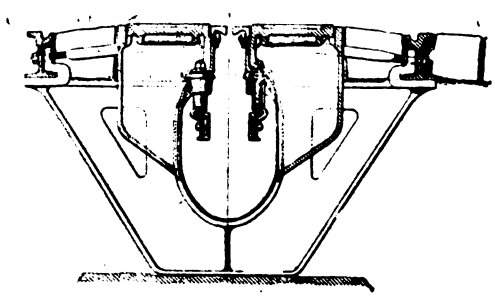


FIG. 1.—Section of Conduit—Insulator Suspension.

effects of any drip which would otherwise reach them, and are of channel iron, weighing about 21lb. to the yard. The rails are 4in. deep and are manufactured in 30ft. lengths. They are suspended for most of the way from the yoke by insulators devised for this especial purpose, and are at a depth of 13in. below the conduit slot. Each insulator is held in a cast-iron bracket, into which is tapped a bolt, Figs. 1 and 3. The shank of this bolt is surrounded by an insulating composition to a thickness of about $\frac{1}{4}$in. Surrounding this is $1\frac{1}{16}$in. of mica, and around this $\frac{3}{8}$in. of porcelain or of an insulating compound, both being now tried. The head of the bolt is surrounded by an insulating compound in the socket in which it is embedded. The socket is fastened to the slot rail by two bolts.

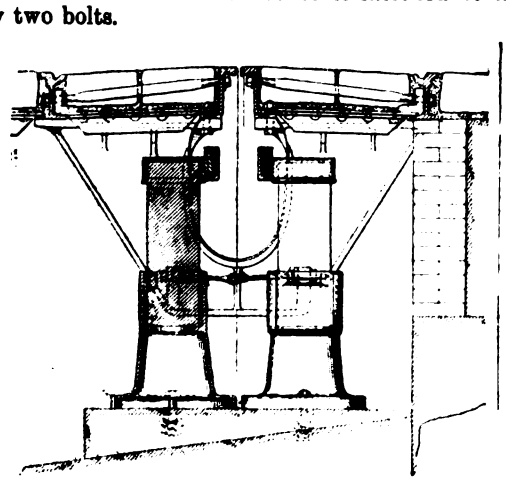

FIG 2.—Section of Conduit—Pedestal Support.

The insulators are located every 15ft., one at each manhole, which are 30ft. apart on straight track, and one at each hand-hole, which are located midway between the manholes. The insulators at the hand-holes are the same as those at the manholes, but the method of attachment is slightly different.

The conductors are bonded to each other by stranded copper wire securely riveted into the web of the metal.

A modification of this system of suspension of the conductors is introduced for a length of about 100 yards of single track on 116th-street, between Lenox and Seventh avenues. This is known as the pedestal method of support. At the manholes, instead of insulators suspended from the ceiling of the conduit, the conductors are supported by a soapstone pillar. The channel bar conductors in this case are 5in. deep, and are set 12in. below the slot. The soapstone pillars are provided with iron caps furnished with brackets, to which the conductors are bolted, and continuous connection is secured by means of a bond of flat copper strips riveted to the webs. The soapstone blocks are set in iron bases erected in the manholes.

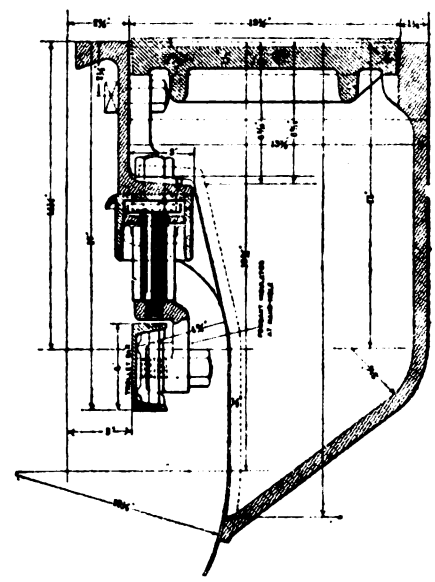

FIG. 3.—Enlarged View of Insulator Suspension at Handhole.

Every twelfth manhole is connected with the power-house by telephone. Quick-break switches are located at intervals in these manholes, in order that any section of the line may be cut out in case of trouble or accident. At the track switches each conductor is provided with a

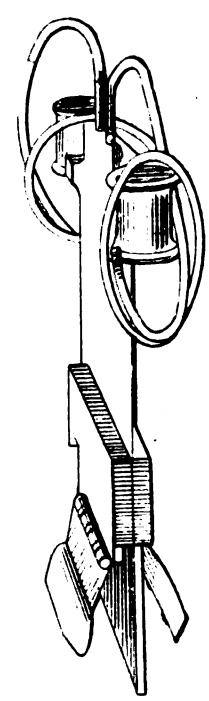

FIG. 4.—Plough.

flaring nose to facilitate the entrance of the plough into the conductors. The manholes in which the insulators are placed are 4ft. 4in. in depth, 4ft. in length, and 14ft. $5\frac{1}{2}$in. in width—that is, the entire distance of the two tracks. They are constructed of brick with 8in. walls that rest on concrete foundations. The floors are laid with 6in. of concrete and are provided with drains for carrying off water. With this provision for drainage no trouble from water in the conduit will, it is believed, be experienced. The conduit was built along the grade of the street, but with sufficient pitch to permit any water flowing into the conduit to

Digitized by Google

find its way into the manholes, located every 30ft., and from thence into the sewers. Each conductor forms one side of the working circuit, and the current is thus insulated through the circuit.

The plough or travelling contact arrangement is also essentially novel. The contact-pieces are of cast iron, and are supported on spring leaves, which cause them to press outwardly against the two conductors, a pressure with about 6lb. The conductors, which are of sheet copper taped, are brought up to the car, and are protected on each side as they pass through the slot by sheet steel. Manganese steel presents evident advantages to this work and will probably be employed. A heavy sheet of fibre is located between the contact shoes to prevent arcing.

The motors employed are the standard General Electric 800 machines controlled by K 2 controllers.

WHELESS ELECTROMAGNETIC RAILWAY SYSTEM.

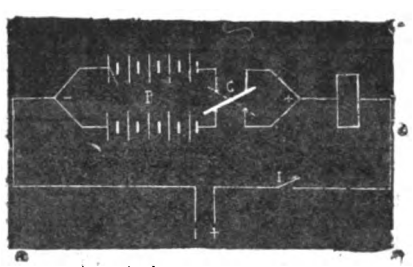
The Westinghouse Electric and Manufacturing Company, U.S.A., have acquired the patents of the Wheless system, which is in operation on the Belt Railway, of Washington, D.C. The apparatus consists of contact-pins placed between the rails and connected to junction-boxes located about 1½ft. outside of the rails on one side. The pins are arranged in groups of three each, and are of chilled cast iron 5in. in diameter. They are set in granite or terracotta blocks, which are bolted to the ties and are connected by a conduit with the junction-boxes. Communication is made to the car by means of collector bars located under the latter, which are of T iron, 2in. by 2in. suspended on springs. These bars are long enough to reach from one set of pins to the next, and at the same time entirely clear the pavement. Two contact-pins of each group are so connected through a magnet in the junction-box that when a current has passed from one pin to the other the magnet is excited, making connection between the feed wire and return, and one of these pins and the third pin. The exciting current is provided by three cells of a storage battery carried on the car and supplying six volts and 15 amperes. When the car has passed, the contact is broken and the knobs are no longer alive. To prevent arcing inside the junction-box the contact surfaces are of carbon, two in number and each about 2in. by 2in. On the railway mentioned, in Washington, a line about three fourths of a mile long on North Capitol-street from New York-avenue to P-street has been in operation for about six months with very satisfactory results. On that line the space between the contact-knobs and the rails where surface leakage might be apt to occur is not even paved. The soil is clay, and in wet weather the mud is on a level with the rails. The surface leakage was about half an ampere, with one car running, with the ground covered with water, and with 500 volts. The Westinghouse Electric and Manufacturing Company is now constructing an experimental line on this system, about one mile in length, at its works in Pittsburgh.

THE GABARRO DRY CELL.*

The following is an account of some experiments which have been made with the dry cell invented by Señor Gabarró-Julien, which has recently attracted much attention in Spain. With elements of comparatively small dimensions, a motor of $\frac{1}{16}$ h.p. was supplied, which drove a Singer sewing-machine with considerable rapidity and regularity. The same battery applied to two small 10-c.p. incandescent lamps, arranged in series, at a pressure of 10 volts, produced a good steady light, quite equal, it is stated, to that of the lamps of same type of the electric lighting companies in Madrid.

The cell consists of a small wooden case, 6¾in. high, 9½in. long, and 6½in. wide. In the upper part there are two small terminals, each in communication with the corresponding electrodes, the positive being a bar of carbon, the negative a cylinder of amalgamated zinc. The chemical substance which acts upon the zinc, working at the same time as a depolariser, is a special paste, the composition of which is the secret of the inventor. The cell, according to documents attested by electricians such as Picou, Fschieret, Volt, and Tommasi, yields a pressure of 12 volts at the commencement of the discharge, which drops after a little to nine volts, which is steadily preserved to the end. The current is of about three amperes, and the interior resistance is about three ohms when the cell is in closed circuit.

The cell has the advantage of cheapness, as, its approximate duration being, it is said, 200 hours, each element costs only about 4s. It has, however, its disadvantages. It polarises itself in five minutes after being in circuit; but, on the other hand, it recuperates at once when switched off without losing any of its qualities, and when the circuit is open there is no internal waste. This drawback—a rather important one where, say, electric lighting is concerned—can, Sr. Villegas observes, be easily remedied by a suitable arrangement somewhat similar to that shown in the annexed cut, where P is the battery distributed in two sets of cells, C the automatic commutator, R the automatic regulator, and I the interrupter, or switch. The automatic regulator is introduced in the circuit with the view of correcting the variations of voltage. Sr. Gabarró constructs the plates of specific dimensions according to the purpose for which the battery is to be used.



Sr. Gabarró-Julien, we are informed, being confident that there will be an extensive demand for his cell, which he has patented in several countries, is about to manufacture it on a large scale.

[It is interesting to note that the Spanish nation is at last waking up and launching its electrical inventions into the world. As is to be expected, their first inventions to be exploited are primary batteries, and we can assure Sr. Gabarró Julien that a perusal of our English papers of 10 years back would have saved him much time in preparing the description of the qualities of his invention. The only item we miss is that of the extremely valuable by-products which these new batteries usually yield. The large demand, however, for these batteries for motive power and light will not come from foreign countries.—Ed. *E. E.*]

EXPERIMENTS ON THE RELATION OF HYSTERESIS TO TEMPERATURE.*

BY FRANK A. LAWS AND HENRY E. WARREN.

(Concluded from page 691.)

The furnace used for heating the specimen was built of firebrick; the external diameter was about 36in., height 18in. Inside the firebrick was a layer of asbestos wool 2½in. thick, kept in place by asbestos board, which was protected by thin sheet iron. The box containing the specimen was made of asbestos board about 1½in. in thickness, and lined with retort cement. During the tests it was tightly closed. The furnace was heated by three blast jets made of gas-pipe; the external tubes were ¾in. inside diameter, the inner tube ⅜in. The supplies of gas and air were regulated by slide valves. The jets were directed into the furnace tangentially and with a slight upward inclination, the effect being to establish a good circulation and keep the interior of the furnace at a uniform temperature.

The specimen upon which the following tests were made

* Señor Gumersindo Villegas, in *El Telegrafista Español* of July 8.

* Contributions from the Physical Laboratory of the Massachusetts Institute of Technology to the *Proceedings* of the American Academy.

Digitized by Google

was composed of so-called French steel, which showed on analysis the following impurities :

	Per cent.
Manganese	0·535
Phosphorus	0·013
Silicon	0·085
Sulphur	0·018
Carbon	0·970

The mass of iron employed was 628 grammes. From this material, which was $\frac{4}{1000}$in. thick, rings of 3in. outside and 2in. inside diameter were stamped, and the specimen formed by piling them. Each was insulated from its neighbours by a layer of pipeclay, applied as a sort of paint, the clay having been moistened with alcohol. Every tenth layer was insulated with mica. The pile so formed was wrapped with asbestos cloth, and the magnetising coil of 36 turns of No. 14 copper wire wound on. The wire was insulated by winding it with asbestos twine. Interwound with the magnetising coil was the B coil of 24 turns. These two windings formed on the outside of the specimen a single layer. The temperatures were determined by a Le Chatelier pyrometer, calibrated by known melting points. The hot junction was placed inside the asbestos wrapping resting against the iron, the leads were brought out through the usual double-cored fireclay tube; this was surrounded by a piece of gas-pipe thoroughly wrapped in asbestos cloth, because in using this pyrometer in a case like the present, where the leads pass from the

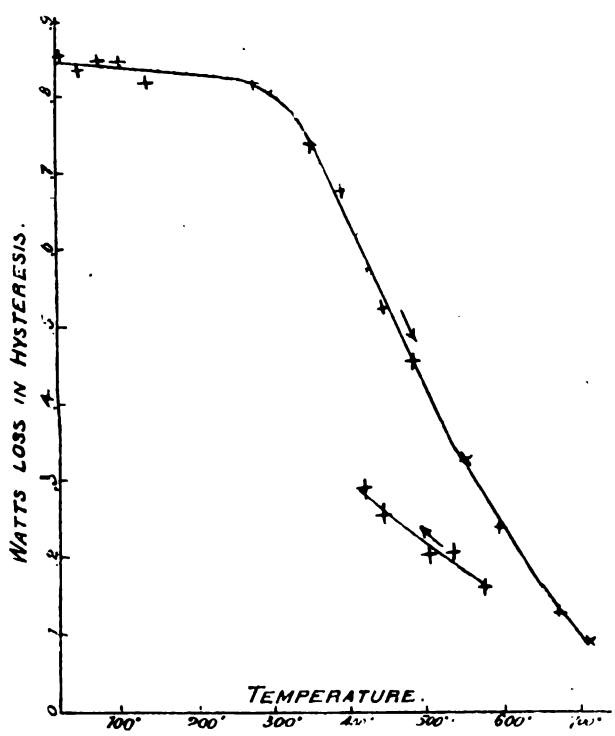


Fig. 3.

hot junction through a space at a higher temperature at a short distance from the junction, it is necessary to guard against conduction along the leads, and consequent errors in the temperature.

The manner of making the tests and the subsequent calculation was as follows: Owing to the construction of the furnace, the specimen being well shielded from the heat of the flames by the internal chamber, the air insulation, and its own asbestos covering, the temperature of the iron rises gradually; consequently, the specimen will be at very nearly a uniform temperature. When a reading is desired, the alternating current is turned on and the B deflection adjusted to its maximum value by K^1, and to its correct numerical value by varying the magnetising current. Watt-balance resistance r_1 is now adjusted, and the pyrometer reading corrected for zero, and dynamometer reading and time observed; after a few minutes the observations are repeated, the temperature having risen in the meantime. This process is kept up until the iron loses its magnetism Occasionally, a direct current was sent through the apparatus and the watt-balance, dynamometer, and pyrometer readings taken; these allow the value of r_1^1 in the hysteresis formula to be determined by making a plot, the co-ordinates being watt-balance and pyrometer readings—from the plot the value of r_1^1, corresponding to any pyrometer reading may be read off. The electrodynamometers were calibrated by sending a direct current through them, and measuring the P.D. at the terminals of a known resistance by projection against the E.M.F. of a Clark cell; the values of deflections and currents squared were plotted, giving straight lines. I^2 was determined by reference to these plots. The zero errors of the dynamometers employed were very variable, and were determined after each reading.

The results of the measurements will now be given. They are plotted as referred to at the beginnings of the several tables.

Table I.—First heating : Ascending curve. See Fig. 3.
B = 1,970. n = 125. W_H = Hysteresis loss in specimen.

W_H.	Temp deg.	W_H.	Temp deg.
·852	23	·678	387
·834	45	·526	440
·845	67	·456	481
·845	98	·331	546
·817	132	·241	595
·809	181	·130	672
818	272	·088	709
·742	347		

The specimen lost its magnetic properties so rapidly that further measurements could not be taken on the ascending curve.

Table I.—Descending.

·407	310	·094	692
·378	345	·104	693
·340	397	·130	693
·321	423	·130	693
·311	438	·142	693
·293	470	·144	693
·258	511	·142	692
·228	555	·140	694
·167	593		

Inspection of the plots shows (Figs. 3 and 4) that for this sample of steel a moderate elevation of temperature, up to about 270deg., has but a small influence on the hysteresis loss; that at this point a change takes place, and the diminution of hysteresis, with rise of temperature, is much more rapid, the decrease being such that at 675deg. the loss is but 13 per cent. of its value at ordinary temperatures. After heating above the inflection point, the specimen

Digitized by Google

shows on cooling a marked decrease of the hysteresis loss from its value at the same temperature on the ascending curve. If the specimen be heated again, a change of direction of the curve takes place, but at a lower temperature. The second plot, Fig. 4, shows an increase of the hysteresis loss after the point of inflection has been reached. As only two heatings were made we were unable to verify these observations, the results of which became apparent only when they were reduced. In addition to the experiment at high temperatures the following observations were made: A specimen was made up and the loss measured at the ordinary temperatures. A mean of three measurements gave ·289 watt as W_H. The specimen was then covered with a mixture of solid carbonic acid and ether. A mean of three measurements showed W_H as ·288 watt, showing that there is practically no change of hysteresis for a diminution of temperature to about 80deg.

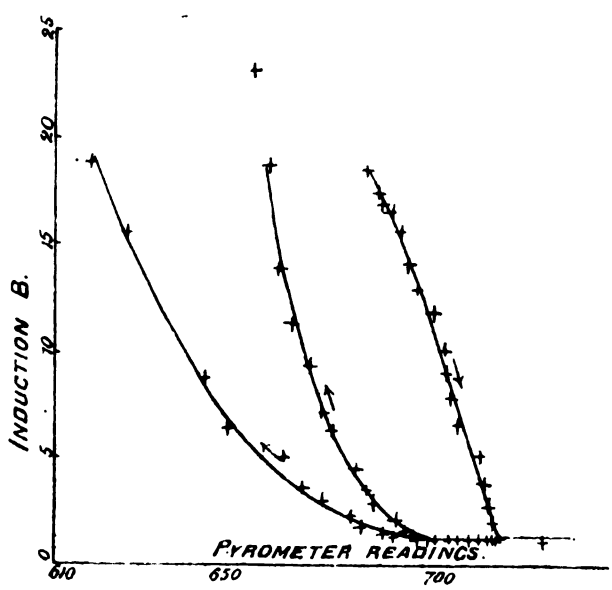

FIG. 5.

Between the ascending and descending observations of the second heating, readings were taken for the purpose of finding whether the temperature at which the iron becomes markedly magnetic on cooling is the same as that at which the sudden diminution of the magnetic properties occurs on heating. Simultaneous readings of the B galvanometer and pyrometer were taken; the current remaining constant, no adjustment for maximum was made. The readings, together with some from the descending curve of the first heating, are given below, and, after being corrected for zero, are plotted in Fig. 5.

TABLE III.

First heating.		Second heating.	
B reading.	Pyr.	B reading.	Pyr.
38·8	7·17	28·1	6·99
38·8	7·10	29 9	7·01
38·8	7·05	31·0	7 02
38·8	7·00	32·1	7 03
38 7	6·95	33·4	7 05

		38·75	7·10
		38 75	7 03
		38·7	7·01
		38 65	6 98
		38 55	6·95
		38·25	6·93
		37·85	6·90
		37·1	6 85
		36·5	6·84
		34·1	6·76
		32·7	6 73
		30·7	6 70

Fig. 5 shows that the two points do not coincide, that on the descending being about 12deg. lower than that on the ascending curve. The difference of form of the curves is noticeable, showing that the regaining of magnetic properties on cooling is more gradual than their loss on heating; the sudden exaltation of magnetic properties occurs at the same temperature in the first and second coolings.

At the time of this writing the research has not been fully completed. We are, however, now engaged on further experiments, and hope to present additional data in the near future.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

A copy of memorandum stating the nature of the proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (No. 4) Bill has been published.

Notting Hill Electric Lighting Order, 1895.—The undertakers under this order are the Notting Hill Electric Lighting Company, Limited. The area of supply is a portion of the parish of St. Mary Abbotts, Kensington. The order is to be read in conjunction with the Notting Hill Electric Lighting Order, 1889, and extends the area of supply authorised by that order.

St. Olave Electric Lighting Order, 1895.—The undertakers are the County of London and Brush Provincial Electric Lighting Company, Limited. The area of supply is the district of the St. Olave District Board of Works. The order contains provisions (1) that the undertakers shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy within the remainder of the area on certain specified conditions; (2) for the deposit of a certain sum as security for the execution of works; (3) for the audit of the accounts of the undertaking; (4) for the approval by the Board of Trade of the system upon which energy is to be supplied and the issue by them of regulations for securing the safety of the public and for ensuring a proper and sufficient supply of energy; (5) for the execution of the necessary works and the breaking up of streets, etc., and the alteration of pipes, etc., under streets; (6) for regulating the manner in which energy is to be charged for and fixing the maximum price to be charged; (7) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works; (8) for the supply, use, certifying, inspection, etc., of meters; (9) for the revocation of the order under certain circumstances; (10) for securing that the undertakers shall not purchase or acquire the undertaking of, or associate themselves with, any other company or person supplying energy under any license, provisional order, or special Act within the administrative county of London unless the undertakers are authorised by Parliament to do so; (11) for prohibiting the supply of energy by the undertakers beyond the area of supply otherwise than under the authority of Parliament or under a license granted by the Board of Trade; (12) for prohibiting the use of overhead wires without the consent of the Board of Trade and the London County Council; (13) for enabling the London County Council or the local authority, as the case may be, to require the undertakers to place their mains, etc., in subways where such subways exist.

Strand District Electric Lighting Order, 1895.—The undertakers are the Charing Cross and Strand Electricity Supply Corporation, Limited. The area of supply is the district of the Strand District Board of Works. The order contains provisions similar to those referred to in the case of the St. Olave Electric Lighting Order, 1895, above mentioned.

LEGAL INTELLIGENCE.

DAMAGE TO A CABLE.

On Monday in the Court of Appeal, before the Master of the Rolls, Lord Justice Kay, and Lord Justice A. L. Smith, the case of the "Caloric" was heard.

This was an appeal from a judgment by Mr. Justice Day, sitting in the Admiralty Division. The action was brought by the Direct Spanish Telegraph Company against the owners of the steamship "Caloric." The plaintiffs were the owners of a submarine telegraph cable laid down between the coast of Cornwall and the port of Bilbao, and they claimed damages for injury to their cable caused by negligence or want of care and skill on the part of the defendants or their servants in the navigation of their ship the "Caloric." On November 14, 1894, the ship, which was then bound in ballast from Bordeaux to Bilbao, arrived at Bilbao Bay and anchored in 14 fathoms of water. Shortly afterwards a pilot came on board and ordered the master to move from his position. The master was accordingly preparing to heave his anchor when the ship commenced dragging, and it was discovered that her anchor had become entangled with two

Digitized by Google

cables, one of them being the plaintiff's cable, and the other, which was smaller, being a disused cable. The master having brought the anchor to the surface adopted the best measures he could think of for freeing it from the cables, and after the crew had been working with this object for some time, the sea being rough and the wind very heavy, the larger cable began to strand, and at last snapped. Finding that the ship still dragged, and believing that there was imminent danger of her going ashore, the master ordered the smaller cable to be cut. This having been done by chopping with an axe, the anchor was got in, and the ship was able to speed ahead. At the trial the plaintiffs endeavoured to prove that it was their cable which had been cut, but the learned judge who tried the case with the assistance of the Elder Brethren of the Trinity House, having had inspection of the cable itself, came to the conclusion that it had not been chopped with an axe, but that the facts were as above stated. Being further of opinion that there had not been any negligence on the part of the master or crew of the "Caloric," the learned judge gave judgment for the defendants. The plaintiffs appealed to this Court. They admitted that they could not any longer contend that their cable had been cut, but they argued that it was the duty of the master under the circumstances to slip his anchor.

Mr. Cohen, Q.C., and Mr. Butler Aspinall appeared for the plaintiffs; Sir Walter Phillimore and Mr. Holman for the defendants.

The **Court**, without calling upon counsel for the defendants, dismissed the appeal.

The **Master of the Rolls** said there was no doubt that the captain of the "Caloric" had been placed in a difficult position. His anchor had become entangled with the plaintiffs' cable, and while he was taking reasonable precautions to get his anchor free, in circumstances of some danger, the plaintiffs' cable had broken. It was all very well for the plaintiffs now to say that he ought immediately to have sacrificed his masters' property in order to save theirs. But the question was whether he had done anything wrong or negligent, whether he had failed in any duty which was cast upon him by the circumstances in which he found himself. The learned judge in the Court below, who had the assistance of the Trinity Masters, held that the captain had not been guilty of any negligence, and those who were now assisting the Court were of the same opinion. There was no ground for alleging negligence of any kind against the captain. The action therefore could not be maintained, and the appeal must be dismissed.

The **Lords Justices** concurred.—*The Times.*

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ille-sur-Tet.—Le Mairie d'Ille-sur-Tet, Pyrénées-Orientales, invites tenders by August 11 for the concession of the electric lighting of the town.

Brussels.—Le Gouvernement Provincial invites tenders by August 2 for a concession for the construction and working of a tramway from the Bourse in Brussels to Koekelberg and Jette-Saint Pierre.

Dortmund.—The Stadtgemeinde invite tenders by August 14 for the construction of a large electric central station. Conditions and plans may be obtained for one mark from Das Magistratsamt, Dortmund, Germany.

Belfast.—The Corporation Electric Light Committee invite tenders by July 24 for the construction of street culverts, insulated cable, copper strip, insulators, etc., for one year. Particulars are obtainable from the engineer at the central station, Chapel-lane

Brighton.—The Corporation invite tenders by August 10 for the supply and erection at the electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping. Specifications can be obtained from the town clerk. Further particulars appear in our advertisement columns.

Whitehaven. — The Town Council invite tenders for (among other stores) electric fittings and incandescent lamps as may from time to time be ordered during the year ending July 31, 1896. Applications for forms of tender must be made to the borough engineer and surveyor, Town Hall, Whitehaven, and sealed tenders, addressed to Mr. Thomas Brown, town clerk, Town Hall, Whitehaven, must be delivered by 10 a.m. on 26th inst.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep burning at the same time 2,200 8-c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Bristol.—Tenders are invited for the supply of (a) pea nut coal, washed; (b) pea nut coal, unwashed, to the electrical lighting station, Temple-back, Bristol, for 12 months from August 1, for the Electrical Committee. A copy of specification and forms of tender can be obtained from Mr. Frank Wm. Prosser, secretary, Electricity Department, Temple-back, Bristol. Tenders must be delivered by noon on 26th inst., addressed the secretary, Electricity Department, Temple-back, Bristol, and endorsed "Tender for Coal."

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a *bonâ fide* tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Datchet (Berks.).—Tenders are invited for lighting the village of Datchet, for the Barker's Bridge House Trust, during October to March, with oil, gas, or electricity. The present number of lamps is 33. Any further number hereafter to be erected in the parish to be included at the rate quoted. Tenders may be for lighting partly by one method and partly by another. The lamps must be lighted at sunset and kept alight until 1.30 a.m. The contractor must supply all requirements and fittings for the lamps (the present posts and lamps being available as far as they will serve) for the lighting as above specified, and must keep the lamps clean and in good repair to the satisfaction of the trustees. Tenders must be sent to the trustees of Barker's Bridge House Trust, care of Mr. H. L. Prior, The Priory, Datchet, by 6 p.m. on 20th inst.

Derby.—The Electric Lighting Committee of the Corporation invite tenders for the builder's work in the boiler seatings for three new boilers and in new coal-store, etc., and accessories, at the central station. Plans may be seen on application to Messrs. Bramwell and Harris, engineers, 5, Great George-street, Westminster, S.W., or to the town clerk, Town Hall, Derby, from either of whom may be obtained, on deposit of £2. 2s., to be returned on receipt of a bona fide tender, a printed copy of the specification, form of tender, and bill of quantities. Tenders, on the prescribed form, must be delivered, with the specification attached and unaltered, enclosed in a sealed envelope, endorsed "Electric Lighting—Tender for Buildings," and addressed to Mr. H. F. Gadsby, town clerk, at the Town Hall, Derby, by 12 noon on 22nd inst.

Valletta (Malta).—Sealed tenders will be received at the office of the Receiver-General and Director of Contracts, Valetta, or at that of the Crown Agents for the Colonies, Downing-street, London, until 11 a.m. on August 1, for the supply of materials in connection with the installation of the electric light in the civil and war department buildings in Malta. The materials are comprised under four headings—viz., (1) cables and wires, (2) tools, etc., (3) fittings, fixtures, etc., (4) sundries. Printed forms of tender and of the specifications and conditions may be obtained on application at the above office, Valletta, or at the office of the Crown Agents for the Colonies, Downing-street, London. Each tender must contain the name of the surety whom the tenderer intends to propose for securing the performance of the contract and the payment of the penalties therein established. The surety to be a person residing in the island. No notice shall be taken of any tender not accompanied by a deposit, to be made in the office of the Receiver-General and the Director of Contracts, Valletta, or in that of the Crown Agents in London, of a sum of £5 sterling, to be forfeited to the Government should the party tendering, or his surety, in the event of the tender being accepted, fail to appear for signing the contract within three days from the day of the notice given to them to that effect. If the tenderer is not resident in Malta, his tender must contain the name of an agent residing in the island, to whom, in the same tender, power must be given to represent the tenderer in the contract. Any tenders which may be delivered at the Crown Agents' office must be in sealed packets addressed to the "Director of Contracts, Malta—Tender for Materials for Electric Lighting," under cover addressed to the Crown Agents for the Colonies.

RESULTS OF TENDERS.

Birkenhead.—The tender of Messrs. W. A. Shaw and Co., Stockport, £800, has been accepted by the Town Council for providing a system of fire alarms throughout the borough. After this tender had been recommended for acceptance an error of omission of £85 was discovered. It being still the lowest tender it was accepted as amended.—The Town Council also received the following tenders for the erection of the central electrical generating station in Bentinck-street: Messrs. J. Shaw, Birkenhead £4,900 (accepted); Messrs. Holme and Green, Liverpool, £4,440. After the latter tender had been recommended for acceptance an error of omission of £378 was discovered. The Town Council thereupon decided to take the next lowest tender.

London, N.E.—The following tenders have been received by the Hackney Vestry for the supply and delivery of cast-iron lamp-posts: Staveley Coal and Iron Company, Chesterfield, £10. 10s. per ton; Guthrie and Son, Leadenhall-street, £9; Hulett and Co., Limited, High Holborn, £9; Bagshaw and Son, Limited, Batley, £8. 10s.; J. C. and J. S. Ellis, Limited, Sheffield, £8. 10s.; McDowall, Steven, and Co., Limited, Upper Thames-street, £8. 10s.; J. Muir and Co., West Hartlepool, £8. 5s.; G. Smith and Co., Glasgow, £7. 14s. 7½d.; Newton, Chambers, and Co.,

Digitized by Google

Limited, Sheffield, £7. 10s.; Tee Side Iron and Engine Works Company, Limited, £7. 5s.; Wells Bros., Nottingham, £7. 5s.; Constructional Ironworks Company, Limited, Bow, £7; Richards and Son, Leicester, £6. 15s.; Lucy and Co., Oxford, £6. 10s. and £7; Ceres Ironworks, Limited, Kingston-on-Thames, £6. 13s. 4d.; Jukes, Coulson, Stokes, and Co., Clement's-lane, E.C., £6. 11s. 9d.; E. and F. Wright, Mile End New Town, £6. 10s.; J. Robinson, Sheffield, £6. 7s. 6d.; F. Bradley, Kidderminster, £6 5s.; J. F. Clark and Sons, Moorgate-street, £6 4s 6d.; Alloa Iron Company, £6; Hampton and Co., Walbrook, £6 (informal); Parsons and Sons, Dudley, £6; Skelton and Co., Lime-street, E C., £6; Pontifex and Co., Coleman-street, E.C., £5. 18s. 9d.; Gibb and Co., 99-100, Fenchurch-street, E.C., £5. 10s. (accepted).

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,356.

Telegraph Construction and Maintenance Company.—The Board has declared an interim dividend of 12s. per share.

West India and Panama Telegraph Company.—The receipts for the two weeks ended July 15 were £351 less than for the corresponding period of 1894.

London, W.—Messrs. Drake and Gorham have been entrusted with the electric lighting of Sir Richard Quain's London house in Harley-street. There will be about 120 lights.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 14th inst. amounted to £1,186, as compared with £905 in the corresponding week of last year, being an increase of £281.

Marylebone.—Mr. Brooke Hickling, of the Marylebone Vestry, has carried a motion unanimously on the Vestry for appointing a special committee to consider and report as to the desirability of lighting the parish by electricity.

Poplar.—A letter from the Capital and Counties Electricity Supply Company stating that they proposed to apply for an order to light the district of the Poplar Board of Works has been referred to the Works Committee.

Weston-super-Mare.—Mr. Dubin, a member of the Urban District Council, has complained at a meeting of the body that Mr. Boyden, another member, had "fostered a scheme for electric lighting at a cost of £20,000, which would produce no direct profit for many years."

Anglo-American Telegraph Company.—After placing £6,000 to the credit of the renewal fund, the directors have declared interim dividends for the quarter ended June 30 of 11s. per cent. on the ordinary stock, and £1. 2s. per cent. on the preferred stock, payable on August 1.

Bexhill.—A meeting of the District Council was held on Monday, at which the Highways and Lighting Committee recommended that the water and gas company, with reference to lighting the streets with electricity, should be informed that the Council refused to pledge themselves in any manner. This was approved of.

Hove.—At the meeting of the Urban Council the Works and Improvements Committee reported that on the 25th ult. the electric light post in Church-road, opposite Fourth-avenue, was knocked down by an omnibus and the lamp and lamp column completely destroyed. The surveyor was instructed to reinstate the post.

Appointments Vacant.—Two assistant electricians are required for the St. Pancras Vestry's new electricity works at King's-road. Particulars will be found in our advertisement columns.—An assistant electrical engineer is required by the Tunbridge Wells Town Council at a salary of £100. Applications are to be sent to the town clerk by the 24th inst.

Harrow Electric Light and Power Company, Limited.—This Company has been registered, with a capital of £25,000, to take a transfer of all or any of the powers, duties, and liabilities by the Harrow Electric Lighting Order, 1894, granted to and imposed upon the undertakers therein mentioned, and to carry on business as suppliers of electricity at Harrow, Middlesex, or elsewhere.

Whitechapel.—The Vestry have received a notice from the Capital and Counties Electricity Supply Company, Limited, of their intention to apply on or before December 21 next, by memorial, to the Board of Trade for a provisional order to authorise them to supply electricity for public and private purposes within the area of the Board. It was resolved to consider the question at the next meeting.

Morecambe.—The District Council have held a meeting, at which the Finance Sub-Committee, respecting the purchasing of the electric light works, reported that a letter had been received from Mr. Jowett, secretary of the company, to the clerk, supplemental to the previous correspondence. It was resolved unanimously that the committee should see Mr. Parkinson, of Lancaster, electrician, with respect to valuing the undertaking, etc.

St. James's and Pall Mall Electric Light Company.—The directors have declared the following interim dividends for the half-year ended June 30, 1895: at the rate of 7 per cent. per annum on the preference shares; at the rate of 4 per cent. per annum on the ordinary shares. The sale of current for the quarter ending June 24, representing the supply at 6d. per unit, amounted to £8,598, as against £7,380 at the same rate for the corresponding period of 1894.

Stock Exchange Notices.—Applications have been made to the Stock Exchange Committee to allow the following securities to be quoted in the official list: City of London Electric Lighting Company, Limited—further issue of £200,000 5 per cent. debenture stock in lieu of the provisional certificates now quoted; and Tramways Electrical Traction Company, Limited—15,000 preference shares, Nos. 1. to 15,000, in lieu of the shares of the Tramways Company of France, Limited, now quoted.

Luton.—It was reported at the last meeting of the Town Council that the confirming Bill in reference to the Luton electric lighting received the Royal assent on June 28. A notice has been received from the Bedford Electric Company of their intention to apply to the Board of Trade for a provisional order for the supply of electrical energy within the area of the borough, but the company had since become aware that the Corporation had themselves obtained an order, and have therefore withdrawn the notice.

Heywood.—Alderman Healey, in moving the confirmation of the minutes of the Technical Instruction Committee at the last meeting of the Town Council, drew special attention to that requiring a certain number of students to ensure the formation of a class for any particular subject. There was a desire to promote every study, but the committee would have to discontinue magnetism and electricity, unless those subjects secured a reasonable number of students. Councillor Dearden seconded the proposition, which was carried.

Eastern Telegraph Company.—The directors of the Eastern Telegraph Company, Limited, announce that, subject to final audit, the accounts show, after placing about £100,000 to reserve, a balance available sufficient to pay the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, less income tax, and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both free of tax, on the ordinary shares, making, with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ending March 31.

City of London Electric Lighting Company.—The directors have declared an interim dividend on the preference shares of the Company at the rate of 6 per cent. per annum for the six months ended June 30 last, the dividend to be payable on and after the 25th inst. The gross revenue for the quarter ended with June amounted to £15,984, an increase of £5,669 compared with the corresponding quarter of last year. The equivalent of 8-c.p. lamps connected at the end of June was 159,250, an increase of 10,656 on the quarter, and of 60,110 compared with the corresponding quarter of last year.

Richmond (Surrey).—A letter from Mr. A. J. Lawson, engineer and manager of the Richmond (Surrey) Electric Light and Power Company, Limited, giving notice of their intention one month after the service thereof, to commence the execution of the works thereinafter described—viz., laying electric conductors along Ormond-road from Hill-street to site of new church, Petersham-road from Vineyard (Hill-rise) to Ivy Hall, in Lancaster-park, and also in Ellerker-gardens, Onslow-road, Montague-road, and Friars' Stile-road—was left in the hands of the Electric Lighting Committee at the last meeting of the Town Council.

St. Saviour's, S.E.—The Sanitary and Sewers Committee have reported to the Board of Works they had considered the question of a new underground public convenience at the junction of Southwark-street and Blackfriars-road. They also instructed the surveyor to prepare plans of the building, and an estimate of the cost had been submitted amounting to £1,725, exclusive of £125 allowed for diverting electric and other mains and removing the existing lamp-column. They recommended that the plans and estimates should be approved. Mr. Newton moved the adoption of the report, which, after a short discussion, was agreed to.

The Victoria-embankment.—We last week printed the report of the Highways Committee of the London County Council on the subject of the electric lighting of the embankment. At last Tuesday's meeting the matter was postponed for a week or two. In addition to Mr. Thornton's amendment, which we have already noted, Mr. Mr. E. White has given notice of the following amendment: "That the recommendation be referred back to the committee with instructions to ascertain and report what is the cost of the present lighting, what would be the cost of incandescent gas lighting, and what would be the cost of electricity supplied by a company."

Galloways, Limited.—This Company has been registered, with a capital of £115,000 in £100 shares, to acquire as a going concern the business and undertaking of a company with a similar title (incorporated April 3, 1889), in accordance with an agreement expressed to be made between the old company and Joseph W. Pollitt, the liquidator thereof, of the one part, and the new company of the other part; and generally to carry on business as engineers, boilermakers, iron and brass founders, rivet makers, copper and tin smiths, millwrights, machine and engineering toolmakers, general contractors, metal workers, steel converters, electricians, suppliers of electricity, consulting engineers, etc.

Fire at the General Electric Company's Works.—With reference to the fire which occurred at the Manchester works of the General Electric Company, Limited, on Friday last, we are informed that the business will in no way be interfered with, and that any orders received will continue to be executed promptly. The heavy stock in the warehouses in London, Manchester, and Glasgow, as well as the manufacturing capacities that the Company have in their various works and shops at Hammersmith, Clerkenwell, Thames-street, etc., will enable them to meet all emergencies for the next few months. In the meanwhile they

Digitized by Google

are pushing forward with all possible speed the erection of plant, machinery, and tools in their new works—Peel Works, Adelphi, Salford.

City and South London Railway.—The returns for the week ending July 14 were £848, compared with £882 for the corresponding period of 1894, being a decrease of £34. The total receipts for the half-year 1895 are £1,763, as compared with £1,761 for the corresponding period of 1894, being an increase of £2 The accounts for the half-year ended June 30 show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1¼ per cent. per annum, carrying forward a balance of £965 to the new account. The dividend for the corresponding period last year was at the rate of 1 per cent. per annum, the balance carried forward being £1,336.

Copper.—"The increase in the visible supplies of copper, upon which we commented a fortnight ago," says the *Financial News*," has proved to be very short-lived, and the pressure of a growing trade demand is making itself felt, as we have all along asserted that it would do. Compared with June 30, there was on the 15th inst., according to Messrs. Merton and Co.'s circular, a decrease in stocks of nearly 1,000 tons, and, including shipments on the way from Chili and Australia, a total decrease from 58,182 tons to 56,911 tons. The price of Chili bars and G.M.B.'s has in the meantime risen from £42. 7s. 6d. to £44 per ton. If the improvement in trade makes the headway it is expected to make under the influence of a strong Constitutional Government, we may look for a greatly increased consumption of copper and a still further shrinkage in the available supplies. That copper will be much higher before the year is out there seems no reasonable room to doubt."

Surbiton.—At the last Town Council meeting the Electric Lighting Committee reported as follows: "We have received a notice from the Capital and Counties Electricity Supply Company, Limited, stating that they intend to apply before December 21 next to the Board of Trade for a provisional order to authorise the said company to supply electricity within the area of the jurisdiction of the Surbiton Urban District Council. We have directed the clerk to inform the company that the Council intend to light the district themselves under the order they have already obtained. We recommend that at least six firms should be invited to send in plans and specifications, with an estimate of the expense of lighting the district; and that if we require it we should be authorised to appoint some engineer of eminence to supervise and select the most eligible plans sent in by the firms who tender." The report was adopted, on the motion of Mr. Williams.

The Douglas Tramways.—The Tynwald Court Committee appointed to consider the petition of the Isle of Man Tramways Company and the Douglas Town Commissioners for leave to introduce a Bill to authorise the laying down and working of a tramway to the upper part of the town, and to confirm and approve a provisional agreement made between the Douglas Town Commissioners and the tramways company, met at Douglas on Tuesday, Deemster Gill presided. Evidence was given by Mr. J. Moore, civil engineer, Mr. William Mackenzie, tramway owner, and Mr. William Henry Andrews, secretary of the London Tramways Company, in favour of a cable system of tramways as opposed to any other form of traction, and agreed that the tramway company's offer of a minimum sum of £15,000 a year for the extension of the lease on the shore front for 21 years was a most satisfactory offer. At the conclusion of the evidence, the committee reserved their decision till Tuesday next.

Fulham.—The Electric Lighting Committee of the Fulham Vestry have reported to the Vestry that they considered there were reasonable grounds for supposing that electric lighting, in conjunction with a dust destructor, could be installed in the parish at a profit to the ratepayers. The Capital and Counties Electricity Supply Company having given notice of their intention to apply for an order to light the district by electricity, the committee reported that they considered that the Vestry would do well to keep the lighting in their own hands. Messrs. Kincaid, Waller, and Manville had therefore been asked whether they were willing to report, for a fee of not more than £50, whether the suggested installation could be carried out in such a manner as to prove a source of profit to the parish. The experts are to be asked what are the most striking features of the present leading systems of electric lighting systems of electric lighting combined with the utilisation of parish refuse.

New Mains.—The London County Council have approved of the following new electric lighting mains being laid: by the County of London and Brush Provincial Electric Lighting Company, Limited, in Garnault-place, in and across Exmouth-street, across Farringdon-road into Rosebery-avenue subway, and in Great Warner-street, Dorrington street, Clerkenwell-road, and part of Farringdon-road, under the County of London (North) Order of 1892; by the same company in Putney-hill, under the Wandsworth Order of 1892; and by the Westminster Electric Supply Corporation in Chapel-place and both sides of Chapel-mews. Notices were also received by the Council from the Vestry of Hampstead, under the Hampstead Order, 1892, of intention to lay mains in Inglewood-road and West End-lane; and from the Vestry of Islington, under the Islington Order, 1893, of intention to lay mains in Paradise-row. The respective vestries are the undertakers under the orders, and the Council has no power of approval or disapproval of works.

West African Telegraph Company.—The report of the directors for the 12 months ended December 31 last states that the Company's revenue for that period amounted to £64,761, against which £17,286 is charged for ordinary expenses and £13,473 for expenditure relating to repairs of cables, etc. After providing for income tax and revaluation of currency assets, there remains a balance of £33,058. From this balance there have been deducted £11,900 for interest on debentures and £11,766 for sinking fund, leaving £9,391, which has been carried to the general reserve fund. In a circular accompanying the report the directors state: "It will be seen that the sum of £9,391, net revenue on the year's working, has been placed to the credit of the reserve fund. This is simply replacing the amount taken from this fund last year on account of heavy repairs. We are now in a sound financial position. With respect to the year 1895, the result of the first six months' working justifies your directors in paying an interim dividend of 2s. per share, which is at the rate of 2 per cent. per annum, and will be payable on the 26th inst."

Yarmouth.—At the last Town Council meeting a letter was read from the Local Government Board, forwarding sanction to the Council borrowing on loan the sum of £17,500 for purposes of electric lighting, repayable in 25 years. The Electric Lighting Committee stated in their report that since their last meeting applications had been received from five customers for 178 lamps, making the total number of customers 92 for 4,700 lamps. The expenditure for the month had been £99. 8s. 4d. and the income £80. 0s. 8d., showing loss on the month's working of £19. 7s. 8d. Stores were required to the amount of £56. 9s. It was desired that the oil-feeding apparatus should be proceeded with. The cost of buildings, tanks, and works which could be carried out locally was £45, and about £60 was the cost of the apparatus from the manufacturers. This expenditure would be paid for out of the loan of £17,500, for which they now had the assent of the Local Government Board. The committee recommended the Council to order the stores and oil-feeding apparatus named in the above report. The report was adopted without discussion.

Scarborough.—The Lamp Sub-Committee, having considered the tender received from the Scarborough Electric Supply Company, Limited, for the lighting of certain streets in the borough with the electric light at a cost of £915. 5s., and also a report prepared by the borough surveyor as to the lighting of the same streets with gas at a cost of £349. 12s. 9d., it has been agreed that the matter should be referred to the Sanitary and Lighting Committee for consideration. At a later meeting of the whole committee the foregoing minutes were approved and confirmed and it was resolved that the proposal to light certain streets in the borough with the electric light could not be entertained at present. Mr. J. W. Woodall wrote stating that he had an offer from an exhibitor to find electric current for a 1,000 c.p. arc lamp to illuminate the exterior of the Fishery Exhibition building, and asking permission to erect other two lamps of 500 c.p. each on iron posts at least 20ft. high on the outer footpath side, or one lamp on the outside of the wall with reflectors, so that no direct light should be shown seawards. The permission was given with certain restrictions.

Aberystwith.—The Town Council have held a meeting at which the following letter was read: "Dear Sir,—Owing to circumstances over which I had no control I was compelled to shut off the electric light last night (July 5) at 10.15, but am pleased to say that I was enabled to light up again after 14 minutes' stoppage. The real cause of the stoppage was the outbreak of one of those complaints to which every dynamo machine is liable—viz., a slight fault in the construction of the machine, and one which often baffles the most expert until it shows itself. I shall be glad if you will inform your Corporation that I have remedied the defect, and that the same fault cannot possibly occur again. I much regret that this should have happened, occurring as it did at a time when the light was probably much needed.—Yours, W. J. Breach, chief electrician." The Finance Committee, in their report, recommended the erection of two additional electric light lamps; and, after some discussion, the recommendation was agreed to, and it was left to the committee to decide whether the lamps should be used in the winter in place of one or two on the Terrace.

Cardiff.—A meeting of the Lighting and Electrical Committee of the Town Council was held on Tuesday afternoon, at which the borough engineer, Mr. W. Harpur, submitted the estimate for the electric works and plant, which showed the estimated sum of £32,500 had been exceeded by £5,000, and he recommended that they apply for powers to borrow an additional £7,500 for the proposed extension and other purposes. He also submitted an estimate of the working expenses for the ensuing six months for the whole of the lighting department (including gas and electricity), which he put at £5,580. 10s., a sum almost identical with that of the last budget, which was £5,556. Mr. Harpur reported that at the request of the Mayor he had had an examination made at the corner of High-street, where Mr. S F. Walker had complained of corrosion setting up in the electric lighting mains, and he found the pipe indicated in as good a condition as when it was laid down. Mr. Ritches said it was only fair that this contradiction should be made known. Mr. Brain: Mr. Walker made a mistake. Mr. Harpur: He may have seen an old water or gas pipe.—The chief librarian at the free library has been instructed to obtain a sketch for electric fittings for the library.

Taunton.—The Electric Lighting Committee presented the following report at the last meeting of the Town Council: "Your committee have received tenders for supplying and fixing a main switchboard at the works. They recommend, provided Messrs. Newton will enter into a contract to carry on the work in accordance with the specification and conditions prepared by Dr. Fleming, that their tender be accepted for the sum of £390. Your committee recommend that tenders be invited from the British Thomson-Houston, Limited, the Westinghouse Company, Limited, Siemens Bros., Limited, Crompton and Co., Limited, and

Digitized by Google

Messrs. Johnson and Phillips for an alternator and exciter for the works, in accordance with a specification prepared by Dr. Fleming." The report was adopted on the motion of Councillor Potter, who explained that Dr. Fleming had advised the committee again and again not to be influenced by lowness of price when purchasing electric light plant. Dr. Fleming had pointed out that although one machine might be lower in price than another, it might turn out to be dearer in the long run than a machine that cost more to purchase, simply because of the loss of generative power. The Council might therefore rest assured that Dr. Fleming, in recommending the purchase of Messrs. Newton's switchboard, had taken this point into consideration and it was consequently a source of great gratification to the Electric Lighting Committee to be able to recommend the Council to adopt Messrs. Newton's apparatus, especially as it was not only deemed by Dr. Fleming to be the most suitable for the purpose for which it was required, but was also the lowest in price.

Loans.—Upon the recommendation of the Finance Committee, the London County Council on Tuesday agreed to lend the Hammersmith Vestry £7,000 for the purchase of land upon which to construct an electric lighting station. The Council on April 2 last agreed to advance the Vestry of Shoreditch £2 000, repayable within 54 years, £1,070 of which was ascribed to the street improvement in Bowling-green-walk, and £930 for land for the electric lighting station. The loan has not been taken up, as the Vestry wishes it to be increased by a further sum of £687. It appears that of this additional sum £107 is wanted for the acquisition of the freehold and other interests in 6, Bowling-green-walk, and the balance, £580, for purchase of the leasehold interest in 25, Coronet-street. The Finance Committee recommended: "That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of Shoreditch for a loan of £687, to defray the cost of purchasing the interests in 6, Bowling-green-walk and 25, Coronet-street, to provide an enlargement of the site for an electric lighting station, be granted, on condition that the loan be taken up at once, interest being charged thereon at the rate of £3. 10s. per cent. per annum, payable quarterly on January 31, April 30, July 31, and October 31 in each year, and the principal being repaid by equal annual instalments on each April 30 as to £107 within a period of 54 years and as to £580 within 30 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the consolidated loans fund." This was approved of.

Chili Telephone Company, Limited.—The report of this Company for the year ended March 31 states that a small addition to the tariff made in October caused some subscribers to withdraw, but others have been connected, making the aggregate number at all centres 4,015 at the end of the 12 months, as compared with 3,987 at the beginning, or a gain of 28. The gross revenue from all sources was 555,551dol., as compared with 504,188dol., an increase of 51,363dol. Owing to the additional expense incurred by reconstructing some of the trunk lines which were in bad condition, the expenditure in Chili was exceptional, amounting to 364,477dol, as against 324,536dol.—an increase of 39,941dol. The net income in Chili from all sources was 191,074dol, as against 179,652dol.—an increase of 11,422dol. The average rate of exchange for the year was 13·61d., as compared with 13·96d., giving a fall of 0·35d. Converted into sterling at these rates, the Chilian figures are £10,835, against £10,448—an increase of £387. The liquid assets and liabilities in Chili on March 31 were valued at 16¾d, the current rate of exchange on that day, as compared with 13d., at which they were valued in the previous year. The increase in the value of the liquid assets over liabilities in Chili, due to this rise in exchange amounts to £2,751, which has been carried to the reserve fund, raising it to £11,852 The expenditure in London is £116 less. The net profit of the whole business was £6,013, as compared with £3,528, an increase of £2,485. The directors recommend the payment of a dividend of 2s. 6d. per share, being at the rate of 2½ per cent. per annum free of income tax, leaving £513 to be carried forward. The capital outlay in sterling was £3,845. The general manager in Chili reports that prospects are encouraging, and affairs improving in every direction

Yorkshire House-to-House Electricity Company, Limited.—The directors have issued the following prospectus to the shareholders: "In view of the increasing demand for electricity in the city of Leeds, the directors have decided upon a considerable extension of the Company's plant and buildings, to meet the anticipated requirements for the winter of 1896. The existing buildings being now filled with plant, the directors are considering plans for a new engine and boiler house on the remaining land of the Company, and propose to instal, in the first instance, additional plant of at least 1 000 i.h.p. These extensions will involve a large expenditure, and the directors have therefore decided to raise the required capital by the issue of shares unallotted. The 9,900 ordinary shares still unissued are now offered at par (£5) to the shareholders, who may apply for any number not exceeding their present holdings respectively. Should any shares remain unapplied for they may be disposed of as the directors determine. A deposit of 10s. per share is payable on application, and a further sum of 10s. per share on allotment. No further call will be made payable before January 1, 1896. Subsequent calls will not be made at intervals of less than three months, and no call will exceed £1 per share. As the Company's ordinary shares have been recently dealt in at a premium, shareholders making application will obtain the advantage of any increase in the market value. Forms of application and copies of the original prospectus may be obtained from the secretary. The contracts and documents referred to in the prospectus may be inspected at the offices of the Company. Applicants for shares will be considered to have notice of any other contracts and to have waived further compliance with Section 38 of the Companies' Act 1867, and allotments will only be made on this footing. Applications for shares must be made on or before August 1, 1895."

Electric Plant.—Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle-on-Tyne, have been entrusted with the contract for the electric lighting of Grey Towers, the residence of Mr. A. J. Dorman. This installation will be of a particularly complete character when finished, and will consist of Cornish boiler 18ft. long by 5ft. 6in. diameter, supplying steam to one of Scott and Mountain's vertical high-speed steam-engines, the engine driving on to an Admiralty-type shunt-wound dynamo feeding accumulators capable of storing current for 225 lamps. The installation will consist of about 250 lamps in all throughout the house and stables. In addition to the electric lighting, Mr. Dorman has decided to drive the laundry machinery by electric motors, and the pump for supplying water to the house will be driven in a similar manner. It is further contemplated carrying the cables to the home farm, where the farm machinery will be driven by electric motors. Messrs. Scott and Mountain are extremely busy in their electrical department, and also in general engineering work. In the former department they have in hand a large electric pumping plant for the Lothian Coal Company, for their Newbattle Collieries Dalkeith, N.B.; electric haulage plant for the Hickleton Main Colliery; together with complete coal cutting plants for the Nostell Colliery, Wakefield, also the Roughrigg Colliery, in Scotland. In the engineering department they are equally well employed, being busy with electric light engines, including an engine capable of giving 200 effective horse-power for the Nostell Colliery. The firm have also a considerable number of their improved type of feed, fire, and bilge pumps in hand for H.M.S. "Venus," "Diana," and "Mars." The Admiralty have recently decided to adopt electrically-driven fans for the ventilation of warships, eight of the firm's improved fans being in hand for H.M.S. "Venus" and "Diana," and H.M.S. "Juno" and "Doris."

National Telephone Company.—The report of the directors for the half-year ended June 30 last states that the income accrued in respect of the business of the half-year amounts to £393,855 as compared with £359,891 for the corresponding period of 1894, being an increase of £33,963. The working expenses for the half-year amount to £206,888, as compared with £187,089 for the corresponding period of 1894, being an increase of £19,799. The net result for the half-year (after deducting the Post Office royalties, amounting to £35,263) is a profit balance of £151,703, as compared with £140 533 for the corresponding period of 1894, being an increase of £11,169. The rentals carried forward for unexpired terms of running contracts amount to £390,978, as compared with £345,358 at the corresponding period of 1894, or an increase of £45,619. Out of the available balance of £122,767 shown by the net revenue account the Board recommends the payment of a dividend at the rate of 6 per cent. per annum, less income tax, on the first and second preference shares, 5 per cent per annum, less income tax, on the third preference shares, and 5 per cent. per annum, free of income tax, on the ordinary shares. The Board also proposes to transfer £35,000 to the reserve fund, and to carry forward the balance of £3,288 The draft of the formal agreement with the Post Office for the acquisition by the Department of the Company's trunk lines having been laid upon the table of the House of Commons, in accordance with the promise of the Postmaster-General, the preliminary agreement requisite to give effect to the arrangements was duly executed and completed on March 15 last. The difficult and somewhat complicated details connected with the transfer of the Company's trunk lines are approaching completion, and payment of the purchase-money, now in process of being ascertained, may be expected shortly. A Parliamentary Committee on telephone questions has had during the past session many sittings, and taken much evidence but has not made a final report. The enquiry stands over till the new Parliament assembles, when it may be hoped the questions submitted to the committee will be speedily determined.

Elmore's Foreign and Colonial Copper Company.—A correspondent of the *Financial News* writes: "The directors of this Company have recently invited the shareholders to subscribe for £7,500 7 per cent. first debentures, secured upon a portion of the Company's securities, the nominal value of which portion is about £87,000. The money is required 'for the purpose of wiping out the remaining few liabilities of the Company, and to enable the Board to deal to the best advantage with the unsold patents and the securities they hold.' The directors further add that 'the security offered is ample; the rate of interest and the bonus on redemption in three years are high' It seems, however, that the response of the shareholders, so far, has not been satisfactory, and an urgent appeal is again being made by the directors for subscriptions *pro rata*. Now, it appears to me that our directors can scarcely be surprised that the priority holders, at least, are somewhat reluctant in subscribing after the treatment which they have received in the past. When the prospectus of the Company was issued it was distinctly and emphatically stated in leading type that the priority holders were to receive the return of the par value of their shares (£5), together with a premium of 100 per cent., out of the first profits of the Company. The £5 was returned out of part of the profits on the sale of the French and German patents; but the whole of the cash profits

Digitized by Google

(some £45,000) made by the sale of the American and Canadian patents were quietly handed over as a loan to the French company, instead of being returned to the priority holders, in accordance with the terms of the prospectus. Not only was this done without the consent of the priority holders (except, perhaps, a few privately consulted), but without first securing sufficient support from the French shareholders to render that loan efficacious and satisfactory. And what is the result? This cash loan of over £40,000 has virtually dwindled down to so poor a security that the directors cannot apparently raise even £7,500 upon it to clear off their liabilities. When it is further considered that according to our last balance sheet the par value of the securities held by the Company amounted to over £160,000, apart from the value of the unsold patents, it is indeed a sarcasm on the past management of the Company to find these liabilities of some £8,000 a very pressing difficulty. Such results as these are not calculated to encourage subscriptions, and if money has to be raised in order to avoid the sale of securities at depreciated prices especially now, 'when,' as the directors say, 'the Company will shortly be able to deal with its assets in a way which cannot fail to be satisfactory to the shareholders,' the call should be upon the holders of founders' shares, to whom the reversion of future profits will chiefly accrue. Clearly, from what has been stated above, the priority holders have virtually handed over already (or it has been done in spite of them) a cash sum equal to a return of £3 per share. Have the founders done as much?"

Sydney Electric Tramway.—We have received the report of the New South Wales Department of Public Works for the year 1893-4, in which a description is given of the Military-road electric tramway, Sydney: "The generating plant of the Military-road consists of a Westinghouse compound engine, with 9in. and 14in. cylinders, taking steam at 400lb. to 110lb. from the main boilers, and driving by belt a Thomson-Houston generator at 900 revolutions, giving 500 to 550 volts. The line wire is of hand-drawn copper, 0·324in. diameter, and the total resistance of the circuit of five miles is 1·3 to 1·7 ohm, according to the weather, the extremes being in very wet and long-continued dry. The insulation of the line is remarkably high, being upwards of one megohm per mile. Fluid insulators are used. There are no feeders or auxiliary insulated conductors, but at the opposite end of the line to the power station is a small accumulator-house, containing a battery of 220 Planté cells of the simplest possible description, each having about 14 square feet of active surface. These cells are cylindrical, entirely of sheet lead, the outer cylinder being also the containing vessel, and are 12in. diameter by 10in. high. They were electrically formed solely by a few reversals of the current when first set up, and since then they have been twice reversed after long periods. The battery will discharge up to 60 or 70 amperes, and already holds sufficient to drive a car home from any part of the line in case of the power being cut off at the station. The capacity will increase with use, and, as far as can be seen, they are practically indestructible. But the great value of the accumulators consists in the help they give to the power plant by supplying the sudden drafts made upon the latter, either in starting the cars or in running up steep gradients, and so enabling the line not only to be worked economically without feeders, but with comparatively small engine power. During the periods when the cars are standing or going down hill, the power is being stored by the accumulators. The motors are of the smallest Thomson-Houston type, double reduction, with one exception: this is a single-reduction motor of 30 h.p., and the gears run in oil in dust-proof casing. Mr. Justin M'Sweeney was a successful tenderer for the extension along Military-road, North Sydney. Work was commenced in October, 1892, but owing to the question of motive power not having been decided upon was not opened for traffic until September 16, 1893, although the line had been practically completed for some months previous. This extension, which is two miles eleven chains in length, single track, joins the cable tramway at the intersection of Miller and Falcon streets, and thence along the Military-road to its junction with the Spit-road. The motive power adopted was electricity, the plant which had been previously working the Waverley-Randwick extension being transferred to North Shore, and located in the cable tramway power-house. The work carried out by this branch in connection with the electric system consisted of the supply and erection of a third boiler by Messrs. Hudson Bros., the alterations to power and car house were carried out by Messrs. Grant and Matheson, and the construction of the junction at the intersection of Miller and Falcon streets by Mr. Justin M'Sweeney. The amount expended on the works was £1,591. The amount of Mr. Justin M'Sweeney's contract for the construction of the permanent way was £6,053."

Windsor.—The Urban District Council have held a meeting at which the following appeared on the agenda: "Alderman Dyson to ask the chairman of the Electric Lighting Committee how far the question of producing the electric light by water power for the use of the town has been considered, and what progress has been made in the subject generally; and, further (the provisional order being assured), when will the all-important question of who shall carry out the scheme—the Corporation for the ratepayers, or the ratepayers for themselves—be considered?" Alderman Dewe, in reply, made a statement as follows: The matter was in the hands of Mr. Medhurst, and the committee were awaiting a report from him. There had been no loss of time. On June 2 a letter was received from Mr. Medhurst asking for information on behalf of his client, Mr. Liardet. He (Mr. Dewe) declined to take the responsibility of authorising the information to be sent, and on June 5 directed a meeting of the committee to be convened. On June 10 he received a letter from Mr. Medhurst complaining of some little delay in sending the information; the committee met on the 11th, when the following resolution was passed: "That the town clerk be authorised to write to Mr. Medhurst and ask him, first of all, to obtain a letter from his client indemnifying the Council against any expense unless the scheme is carried out, and that on the receipt of such letter the required information be furnished." On June 14 a copy of the resolution was sent to Mr. Medhurst; on June 17, Mr. Medhurst replied that he would at once write to Mr. Liardet for the letter required, and send the original to the town clerk, and would keep a copy. On July 2, a letter was received from Mr. Medhurst enclosing a letter from Mr. Liardet; on July 3, a plan was sent, and the surveyor witten to to send the other particulars. These particulars were now in the hands of Mr. Medhurst and Mr. Liardet, and directly the committee heard from them they would meet and consider Alderman Dyson: What has been done with regard to the water power? Alderman Dewe: I can only say that it is under the consideration of Mr. Medhurst. We are to have a general report not only on the best means of supplying light and water power, but a refuse destructor. Councillor Burt said Alderman Dyson must have felt obliged to the chairman of the Electric Lighting Committee for his courtesy in answering him so explicitly. Much seemed to have taken place since the last meeting of the committee. In Alderman Dewe's statement there was much information of which the committee should be cognisant. Was it advisable to make known to the Council general information of that kind before it came to the committee? He meant the letter received on July 4. The Deputy Town Clerk informed the Council that the electric lighting order granted to the Council by the Board of Trade had now become an Act of Parliament. It was passed among other unopposed Bills. The Council could set to work to carry out the supply of electric light to the town of Windsor, or pass resolutions empowering other people to supply it. Councillor Clarke: What was the cost of getting the order passed? The Deputy Town Clerk: I am not in a position to say precisely, but it will not exceed what was estimated—£250. Alderman Dyson said he had to thank Alderman Dewe for the information he had given him and the trouble he had taken to obtain it. He thought his question would show his anxiety that the work should be proceeded with The sooner the Council, having obtained the order, buckled to, the better it would be.

Harrow.—Plans of an electric light station in West-street, near the entrance to the Church Fields, were submitted to the District Council at their last meeting and approved. The clerk read the following letter: "To the chairman and members of the Harrow-on-the-Hill Urban District Council, successors to the Harrow Local Board,—We, the undersigned, Rookes Evelyn Bell Crompton and William Charles Cloete Hawtayne, hereby notify to you that we name the Harrow Electric Light and Power Company, Limited, as our nominees under the agreement of December 28, 1894, between the Harrow Local Board and ourselves for the transfer of the Harrow Electric Lighting Order, 1894. And we hereby request you to advertise and deposit the draft deed annexed to the said agreement, and in due course submit the same to the Board of Trade for their approval as required by the fifty-ninth section of the said order. At the same time we beg to hand you 20 printed copies of the draft deed for depositing and supplying to persons requiring the same.—(Signed) R. E. Crompton and W. C. C. Hawtayne." Mr. Saunders complained that they were giving the company the monopoly, whereas if they had gone to the Board of Trade for the order themselves the monopoly would not have been given to them. Could any of them, with the interests of the ratepayers at heart, really create a monopoly for 20 years? The commodity was certain to go down in price, but they would have no ghost of a chance of a reduction in Harrow. Some gentlemen had said they might go to the Board of Trade for a reduction, but that was out of the question, as the company by the deed were to be allowed to take 7 per cent. on their outlay. Where was there an electric light company paying 7 per cent.? It might go down to 2d. a unit in the next 20 years, but in Harrow they would have to keep on paying 8d. per unit That was not a proposal which anybody in their senses would listen to for a moment. He was quite sure the ratepayers of Harrow would not do so. They were going to create this monopoly to benefit nine private consumers. He could not conceive anyone out of a lunatic asylum agreeing to it. The Council might, but they could not debar the ratepayers from signing a memorial which he was going to present. He understood Mr. Fisher was solicitor to the new company, but no man could serve two masters, and he should not act for gentlemen who were their opponents. It had been said that he wanted to choke off the light, but that was not so. What he was hostile to was an iniquitous monopoly. Let the company come to the Council for an annual license. He had no definite resolution to propose, but he wanted them not to appear to approve of the Local Board's action in transferring their order. Mr. Hawkins said there was one outside a lunatic asylum who was prepared to take his stand on the transfer, and that was himself. Mr. Saunders made the order of absolutely no use to the Local Board, and they did well to sell it and save the ratepayers any expense in the matter. The monopoly, as Mr. Saunders called it, would be to the benefit of the town. Dr. Williams suggested whether they were in order discussing a subject with no resolution before them. By dodging their standing orders members who had already spoken could speak again, and that was not fair. Mr. Hawkins said the only business-like step was to grant the transfer, and he moved "that it be granted." Mr. Bradley Smith seconded the motion. Mr. Saunders moved as an amendment, "That Messrs Crompton and Hawtayne be informed that the Council are not prepared to go on with the contract." Mr.

Digitized by Google

Strange seconded the amendment, Messrs. Saunders and Strange voting for it, and the chairman, Dr. Williams, Messrs. Strickland, Bradley Smith, and Hawkins against. Messrs. Dell and Clowes did not vote. On Mr. Hawkins's original motion being put, there voted for it the chairman, Dr. Williams, Messrs. Strickland, Bradley Smith, and Hawkins, and against it Messrs. Saunders and Strange. Messrs. Dell and Clowes again did not vote.

PROVISIONAL PATENTS, 1895.

JULY 8.

13164. **Improvements in alternating-current dynamos.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Maschinenfabrik Oerlikon, Switzerland.)

13168. **Improvements in electrical contact-making devices.** Richard Myers, 323, High Holborn, London.

JULY 9.

13205. **Improvements in electrical transmission of energy for signalling.** Michael Idvorsky Pupin, 46, Lincoln's-inn-fields, London. (Complete specification.)

13207. **Improvements connected with electric arc lamps.** Albert Cooper Seibold, Edgar Olcott Clark, and William Sowdon, 55, Chancery-lane, London. (Complete specification.)

13255. **Improvements in apparatus for the electrolysis of oxides, salts, and other chemical compounds.** Joseph Baxeres Torres, 17, St. Anne's-court, Wardour-street, London.

3274. **An improved arrangement for telephonic apparatus adapted to only register the conversations really held.** Franz Quatram and Ernst Hildebrandt, 18, Buckingham-street, Strand, London.

JULY 10.

13285. **Improvements in electrical switches.** Martin Rohmann, Box 94, Johannesburg, South Africa.

13303. **Improvements connected with arc lamps.** Ernest Albert Pellet, 37, Cursitor-street, Chancery-lane, London.

13312. **A rain-making contrivance to be used in conjunction with the barometer, hydrometer, electrometer, etc., under Government control by wire (telegraph).** Hans Peder Madsen, 43, Upper Marylebone street, London.

JULY 11.

13348. **Improved methods of distributing power by electricity.** Frederick Henry Royce and Ernest Alexander Claremont, Electron, Cavendish-road, Chorlton-cum-Hardy. (Complete specification.)

3380. **Improved electric lighting system for railway vehicles and dynamo therefor.** Morris Moskowitz, Leon Daniel Adler, Abraham Sanford Adler, and Theodore Walter Myers, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13388. **Improvements in electric arc lamps.** James Devonshire, 70, Chancery-lane, London. (Elihu Thomson and Charles E. Harthan, United States.) (Complete specification.)

13389. **Improvements in methods of and means for regulating the speed of continuous-current motors.** James Devonshire, 70, Chancery-lane, London. (Merle J. Wightman, United States.) (Complete specification.)

JULY 12.

13404. **Improvements in dynamo-electric machinery.** Frederick Henry Royce and Ernest Alexander Claremont, Electron, Cavendish-road, Chorlton-cum-Hardy. (Complete specification.)

13405. **Improvements in and relating to electric telephone systems.** Alexander Marr, 70, Market-street, Manchester. (Complete specification.)

13411. **Improved methods of distributing power by electricity.** Frederick Henry Royce and Ernest Alexander Claremont, Electron, Cavendish-road, Chorlton-cum-Hardy. (Complete specification.)

13416. **Improvements in electric lamps for stage lighting.** Austin Walters, 4, St. Ann's-square, Manchester. (Complete specification.)

13426. **An electric polishing machine.** Carl Oppermann, 2, Wynyatt-street, Clerkenwell, London.

13434. **Improvements in the electrolytical production of zinc from its ores and apparatus therefor.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

13436. **Improvements in electric light suspension fittings.** Leslie Bradley Miller, 2, Gray's-inn-road, London.

13438. **Improvements in or relating to telephone switchboards and pushes or calling devices connected therewith.** Jakob Stamm, 46, Lincoln's-inn-fields, London. (Complete specification.)

13444. **Improvements in electrical heating apparatus.** Octavius March, 40, Chancery-lane, London.

13459. **Improvements in the manufacture and production of electric cables or conductors.** George Edward Heyl, 47, Lincoln's-inn-fields, London.

13472. **An improved electric lighting system for road and railway vehicles.** Nicolas Gleboff, 45, Southampton-buildings, Chancery-lane, London.

18274A. **An improvement in electric arc lamps.** James Brockie, 28, Southampton-buildings, Chancery lane, London. (Date claimed under Patents Rule 19, September 26, 1894.

JULY 13.

13483. **Improvements in dynamo-electric and electro-dynamic machines.** Charles Raleigh, 191, Fleet-street, London.

13495. **An improved electrically-illuminated curtain or drop for theatrical purposes.** William Holland, 5, John Dalton-street, Manchester.

13530. **Improvements in telephones.** Anton Hamm, Gergely Blank, Victor Brandt, and Gyula Körmendy, 28, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1894.

835. **Electrolytic apparatus.** Hargreaves and Bird. (Second edition.)

15282. **Ploughing by electricity.** Brutschke and Schimpff.

15617. **Registering number of telephonic conversations.** Münch.

15816. **Telegraph apparatus for marine, etc., engines.** Douglas.

15843. **Telegraphic apparatus.** Boudet and Lacombe.

15858. **Electric railways, etc.** Claret and Wuilleumier.

18359. **Electric elevating mechanism.** Willcox. (Eisenwerk, late Nagel and Kaemp, Actien Gesellschaft.)

19176. **Telephone indicators.** Ericsson.

1895.

8049. **Electric alarm clocks.** Thompson. (Knapp and another.)

9132. **Electric ceiling and wall connectors.** Dorman and another.

9217. **Electric cut-outs.** Verity.

9547. **Attaching electric lamp to a cap.** Lake. (Rodriguez and another.)

10052. **Electric railway signals.** H. V. and H. C. Miller.

NOTES.

The Seel Patent.—It is reported from Berlin that a new company, with a capital of 1,000,000 marks, has been formed to exploit a fresh Seel incandescent lamp patent.

The Telephone in Turkey.—The Grand Turk has long resisted the introduction of the mysterious telephone into his dominions, but, if reports from Constantinople be true, the Sultan seems at last disposed to consent to the erection of a telephonic line between Stamboul and Sofia.

Late News.—The Department of Science and Art has just received information through the Foreign Office that an industrial exhibition is to be held next year at Berlin. Everybody knew this some years ago, but Government departments are notoriously slow in obtaining information.

Electricity in Zinc Production.—An item from Adelaide states that there has been a miniature boom in the shares of some Broken Hill mines known to contain sulphide ores, owing to the discovery by Mr. Ashcroft, electrician of the Proprietary mine, of a successful process of extracting the zinc by electrolysis.

The Black Sea-Baltic Canal.—In connection with the scheme for the construction of a canal from Riga, on the Baltic, to Cherson, on the Black Sea, it is proposed to utilise the water power which the various auxiliary rivers will yield on entering the canal for electric lighting, so that the canal can be navigated at night.

The Electric Light in Italy.—The delightful town of Eboli, or Evoli, 44 miles to the south-east of Naples, is to be electrically illuminated. Hydraulic power will be transmitted electrically from a neighbouring district, and the installation will consist of 100 16-c.p., 70 25-c.p., and 30 50-c.p. lamps. The rate to be charged to consumers will be one centesimo per candle per evening.

Electric Fireworks.—A system of electric fireworks which has recently been invented by a M. Champion is nightly attracting large crowds to the public garden in Angers—so our lively contemporary *L'Etincelle Electrique* (July 20) records. The spectacle is, it seems, varied by luminous electric fountains and by the electro-terpsichorean performances of a mysterious but apparently well-known personage called Loïe Fuller.

Moving with the Times.—In former days fortune-tellers used to think that they did enough when for a shilling or so they promised a young woman three husbands, but Mary Smith, of Manchester, is keeping up to date. She promised one of her visitors a dark young man as a husband, and also that she would be taken by him to a place where there would be a great many electric lights. This was cheap at half-a-crown.

Trans-African Telegraphy. — The Trans-African telegraph line is being pushed rapidly forward. If the transport service between the Shiré and Lake Nyassa does not prove too great a drawback, a cable is to be laid through the latter lake to the northernmost end, and thence the line will follow the Stevenson road to Tanganyika, where another cable service is projected, a land line joining Uganda with the lake.

Michigan Mining School.—We have received a prospectus of the Michigan Mining School, Houghton, Michigan, in which electrical engineering occupies a place. As illustrative of American methods, we may quote the following passage: "The degree of mining engineer will carry with it also the degree of bachelor of science, if the candidate for the degree of E.M. shall make application for the S.B. degree and pay the required fee."

Liverpool Engineering Society.—On Saturday a party of members paid a visit to the Lytham sewage works at the invitation of Dr. L. Fisher, J.P., chairman of the Urban District Council. Mr. Paterson, of the Hermite Company, explained that the system experimentally adopted at Lytham is the Hermite process. After an inspection of the electrical work, of the various manholes on the main sewer, and of the outfalls, the party were entertained by Mr. Alderman W. L. M'Clure, J.P.

Institution of Civil Engineers.—The Association of Yorkshire Students of the Institution of Civil Engineers paid a visit to the West Riding Collieries of Messrs. Pope and Pearson at Altofts on Saturday. The party afterwards proceeded to inspect the surface plant, special attention being given to the elaborate screens and to the coal-washing plant recently erected upon Baum's system. The air-compressing, electric lighting, and winding machinery were also inspected.

Electricity on the Stage.—A dance, entitled "Les Fleurs Electriques," is being given at the Tivoli, in the Strand, by the three Sisters Devereaux. The three lady dancers are covered with electric lamps to represent various coloured flowers. The lamps are worked from off the electric light mains, and are made to change colour with the movements of the dancers and the music, producing a very pleasing effect. The electrical work has been carried out by the Lithanode and General Electric Company, Limited, 64, Millbank-street, S.W.

Electric Organ.—The celestial organ presented to Westminster Abbey by Mr. A. D. Clarke is now set up in the triforium of the south transept, and at Sunday's service was played by Dr. Bridge. Though in all respects a separate organ, complete in itself, it forms part of the grand instrument in the choir. It is controlled from the same console, and may be used in conjunction with the great organ. The action is electric, connection being established by a cable 200ft. in length. Since the organ is not visible from the church below, and is separated from the organist by the full length of the building, the effect when the music breaks forth is very striking.

New Electric Tramway System.—German papers announce that Messrs. Schuckert and Co. have invented a new system of electric tramway traction, by which the disfigurement of the streets through overhead conductors is avoided. Between the rails, at intervals of about five yards, are placed small insulated contact-pins, let into the pavement, which offer no obstruction to the ordinary street traffic, and to which current is conveyed by conductors from the power station. The new system, it is stated, will prove to be much cheaper than the underground conduit method. Thus the German papers. The truth probably is that Messrs. Schuckert have acquired the patent rights for Germany of the Wheless system described in our last issue, page 76.

New Telegraph Instrument.—*Elettricità* of July 21 announces that an official, named Colonna, in the Central Post Office in Rome, has invented a telegraph instrument whose powers of rapid transmission are superior to those of existing apparatus, and which can replace with advantage the Wheatstone instrument that is at present used for the simultaneous dissemination of parliamentary reports to the most important telegraph offices in the kingdom and to the principal daily papers. The laborious translation of the signals which is associated with the Wheatstone system would, it is said, be obviated by the new instrument. The receiving part of the method would, it is added, require no special practice, and the system of transmission could be acquired in a short time.

Prizes Given.—The French Société d'Encouragement pour l'Industrie Nationale has distributed its prizes for 1895. The premium of 2,000f., offered for an apparatus or an industrial process for rapidly measuring or estimating the insulation of the various parts of an electrical installation in operation, has not been awarded; but two consolation, or rather encouragement, prizes of 500f. have been granted to two electrical engineers, MM. Lartigue and Roux. In the list of medals bestowed for inventions or improvements in industrial arts, figures a silver medal won by M. Laffargue for his treatise on the electrical fitter. A silver medal has also been awarded M. Hillairet for the communication which he made to the society in April last on the subject of electric transmission in workshops.

Magnetic Declination.—The variations of magnetic declination, horizontal force and vertical force, and of earth currents, have been registered photographically at Greenwich Observatory. Increased magnetic activity was shown in the year 1894, and great disturbances occurred on July 20 and August 20; the spot of light of the vertical-force magnet on the former date, and the spots of light of the horizontal-force and vertical-force magnets on the latter, having passed beyond the range of the registering sheets for some hours. In these two cases the registers were supplemented by eye observations. In July and August the disturbance in the earth-current registers caused by the South London Electric Railway showed a great increase, which is presumably due to the experiments then being made in the use of motors on the carriages of the railway instead of separate locomotives.

Thermo-Electric Phenomena between Two Electrolytes.—M. Henri Bagard in the *Ann. Chim. Phys.* writes that in continuation of his researches he has determined the thermo-electric E.M.F. in the cases of a number of couples consisting of two electrolytes. The E.M.F. is in all cases, as with the metals, a function of the second degree of the temperature, and very frequently the existence of a neutral point was observed somewhere between 0deg. and 75deg., the limits of temperature of the experiments. In the case of two solutions of the same salt of different degrees of concentrations, the current always travels across the heated junction from the dilute to the concentrated solution. Becquerel's law of intermediate substances and the law of intermediate temperatures are found to hold good. There is a simultaneous inversion of the thermo-electric E.M.F. and of the Peltier effect at the point of contact of the two electrolytes, and an electrical transference of heat in these liquids.

Limits of Electrolysis.—M. Marcellin Berthelot, in *Ann. Chem. Phys.*, states that he has formerly shown by experiment that in the electrolysis of an alkali salt, of which neither the acid nor base is oxidised or reduced during the operation, the minimum E.M.F. necessary for electrolysis is the sum of two equivalent quantities—the one being the heat absorbed in the separation of the acid and the base in dilute solution, the other the heat of decomposition into oxygen and hydrogen of the water holding the substance in solution. In the case, for instance, of potassium sulphate in dilute solution the sum of the two quantities of heat is $15{\cdot}7 + 34{\cdot}5 = 50{\cdot}2$ cal., when one gramme of hydrogen is liberated. This is equivalent to 2·20 volts, a number which Le Blanc has obtained by direct observation. Other results are quoted in support of the above law, which the author maintains as an empirical law, independent of any hypothesis regarding the condition of the dissolved salts in solution.

Influence of Magnetism on Chemical Action. Mr. F. A. Wolff, jun., in the *American Chemical Journal* states that in 1881 Remsen noticed that when copper is deposited from a solution of copper sulphate on a plate of iron placed on the poles of a magnet, it is arranged in ridges round the poles which are at right angles to the lines of force, and consequently coincident with the lines marking the equipotential surfaces. The outlines of the poles of the magnets are always sharply defined on the plate, as along these lines a portion of the iron of greater or less width is left unacted on. The author has investigated these phenomena, and his results and conclusions are contained in this paper. The absence of deposit over the outlines of the pole is not due to any direct influence of magnetism on chemical action, but to the accumulation of the iron salts formed in the reaction about those parts, and to the electric currents arising therefrom. The fact that the deposit is thickest immediately adjoining the protected region also finds its explanation in the electrolysis accompanying these currents. The deposition in ridges is not due to any direct influence of magnetism on chemical action, and is not directly due to the voltaic currents in the liquid. Copper is deposited in ridges on both magnetic and non-magnetic metal when a solution of copper sulphate is allowed to flow over them and the ridges are arranged along the lines of flow. The deposition in ridges when copper is deposited on iron in a magnetic field may be due to similar action.

Another.—The latest recruit to the already fairly serried ranks of electrical journalism in the United States is "*The Electrical Journal*: An Illustrated Review of the Industrial Applications of Electricity, Gas, and Power." As is usual with fresh ventures, our new Yankee cousin defends the inception of its being—and it does so in this fashion: "It is not altogether an uninteresting diversion to see three leading electrical papers chafing over the time-worn moot-point of venerableness, as from information at hand it would appear unquestionable that our esteemed prototype, the *Electrical Engineer*, is really the 'oldest' publication, as it claims, and that our newsy friend, the *Electrical Review*, is entitled to the distinction of being the 'oldest weekly.' As for the 'pioneer' journal, Webster defines the word as expressing 'one who goes before to remove obstructions or prepare the way for another,' or, in plainer terms, a pioneer is one who steps aside that another may pass on. It is advisable, then, if there must be a controversy, that it be confined to the journals named, or the third must either alter its plea or stand convicted on its own evidence. The *Electrical Journal* rests content in the knowledge that no one can dispute the claim that to-day it stands as the 'newest' electrical publication in America, if not in the world, and here, again, the same authority sapiently defines the word 'new' as 'recent, fresh, modern.' Clearly, then, the motto of the *Electrical Journal* shall be: 'The newest electrical publication in America.'" We have no intention to contest the modest claim of our young dime contemporary, which, by the way, is published in the Golden West, at 'Frisco.

Compounding Dynamos for Armature Reaction. Prof. Elihu Thomson read a paper on this subject at the Niagara meeting of the American Institute of Electrical Engineers, in which he described a type of dynamo not claimed to have any commercial importance, except, perhaps, in very special cases, but interesting in several respects. The machine may briefly be described as a four-pole dynamo with windings on only two opposite poles. Under no load the magnetic flux tends to pass entirely through the armature between the "live" poles, while with load the distortion of the field causes some of the flux to be diverted through the "dead" poles. By properly choosing

Digitized by Google

the position and spread of the "dead" poles in relation to the wound or excited poles, and adjusting the magnetomotive force of the initial field relatively to the turns on the armature and the speed of driving, the effect of compounding or over-compounding may easily be obtained. The paper contains curves giving the results of experiments under different loads, showing that a large range in compounding is possible. A feature of the machine which developed itself when carbon brushes were used was that even at heavy loads the brushes could be set back from their maximum position, or true diameter of commutation, and that the movement was attended with little, if any, increase of spark, while the potential steadily went down. It was thus easily possible to adjust the potential by a backward movement of the brushes in the space between the unwound and wound poles, while the slight sparking under the carbon brushes was not increased thereby.

Thermo-Electric Properties of Platinoid and Manganin.—Mr. Benjamin O. Pierce, in the *American Journal of Science*, states that he has had occasion to determine the thermo-electric relations of copper to such platinoid and manganin as are to be obtained in the market. The nature of the results will be seen from the following table. The current passes across the hot junction from the first-named metal to the second; the E.M.F. is measured in microvolts.

Temperatures of the junctions.	E.M.F. Copper *v.* manganin.	E.M.F. Platinoid *v.* copper.
0° and 10°	4·3	189
0 „ 20	9·2	379
0 „ 30	14·1	572
0 „ 40	19·6	769
0 „ 50	25·7	971
0 „ 60	32·6	1,179
0 „ 70	40·2	1,391
0 „ 80	48·1	1,609
0 „ 90	56·4	1,834
0 „ 100	64·9	2,063

The results vary with the thickness of the wires used and the annealing of the metals, but the E.M.F. of no one of the manganin-copper combinations experimented on was greater than about one-seventh that of the weakest of the platinoid-copper combinations under similar circumstances. Hard-drawn manganin wire can be used with advantage as a slide wire, since accidental heating does not alter its resistance appreciably, and the thermo-electric effects at the junctions of the slider would be insensible.

Institution of Mechanical Engineers. — The summer meeting of this institution will be held in Glasgow from Tuesday, 30th inst., till Friday, August 2, under the presidency of Prof. A. B. W. Kennedy, when the following papers will be read: "Hydraulic Stoking Machinery and Labour-Saving Appliances in Modern Gasworks," by Mr. Andrew S. Biggart, of Glasgow; "Notes on Hydraulic Power Supply in Towns: Glasgow, Manchester, Buenos Ayres, etc.," by Mr. Edward B. Ellington, of London; "Recent Engineering Improvements of the Clyde Navigation," by Mr. James Deas, engineer of the Clyde Navigation; "Notes on Modern Steelworks Machinery," by Mr. James Riley, of Glasgow; "Telemeters and Range-Finders for Naval and other Purposes," by Profs. Barr and Stroud; and "The Electric Lighting of Edinburgh," by Mr. Henry R. J. Burstall, of London. Visits will be paid to the Glasgow waterworks, Milngavie; Glasgow sewage works; Dalmarnock Ironworks; the works of the London and Glasgow Engineering and Iron Shipbuilding Company; the Fairfield Shipbuilding and Engineering Company; Messrs. Alex. Stephen and Sons' works, Linthouse; Dawsholm gasworks, Maryhill; Messrs. Neilson's Hyde Park Locomotive Works; Messrs. Sharp, Stewart, and Co.'s Atlas Works; Caledonian Railway Works, St. Rollox; North British Railway Works, Cowlairs; Messrs. Dübs's Glasgow Locomotive Works; Messrs. Alley and MacLellan's Sentinel Engine Works; the works of the Glasgow Iron and Steel Company; and the works of the Summerlee and Mossend Iron and Steel Company. On Saturday, August 3, the Edinburgh Corporation electric lighting station will be open to the visit of members. Among other works in Glasgow and the neighbourhood which will be open to members are those of Messrs. Mavor and Coulson, electrical engineers, Bridgeton Cross.

Cables.—The current number of the *Strand Magazine* contains a popular article by Mr. William G. Fitzgerald on "The Romance of our News Supply," in which he says: "The enemies of the cable are many and various. Sometimes a shark will bite at it savagely, leaving a few teeth in the coating as a memento of the encounter. During repairing operations in the Red Sea, the grapnels brought up a whale's skeleton weighing a ton or so. Then there are ships' anchors, submarine volcanoes, erratic currents, and continuous friction to contend with. The most successful and persistent enemy, however, was until recently the teredo boring worm. Even the teredo worm has now been baffled by the use of brass ribbon. The fact of a breakage is very easily discovered, but the way in which the spot is localised is simply marvellous. I cannot possibly describe the technical routine; let it suffice to say that the galvanometer test is applied, and then a cable-ship is despatched to within perhaps a few hundred yards of the actual breakage, when she uses her grapnels until the broken lengths are brought up. Before the final splice is made, messages are sent from the ship in mid-ocean to the nearest shore station. On certain occasions cable messages are interpreted at the receiving station by means of a brilliant spark which plays along a scale; but almost every message flashed from continent to continent is now recorded by that wondrous instrument known as the siphon recorder invented by Lord Kelvin. The principal parts of this instrument are a light rectangular coil of silk-covered wire and a powerful magnet. The coil is suspended between the poles of the magnet, so that when excited by the electric current from the cable it swings on a vertical axis. Its movements are recorded on a paper ribbon drawn at a uniform speed before the point of a fine glass siphon no thicker than a human hair, which conducts a stream of ink from a reservoir on to the paper ribbon. The marking end of the ribbon responds to and multiplies every movement of the coil, leaving on the ribbon an ink trail which is an exact and permanent record of the movements of the coil under the influence of the currents from the cable, but which the uninitiated might mistake for the trail of a partially-disabled bluebottle that had only just escaped an inky grave. The siphon records from 250 to 300 letters per minute."

Utilisation of the Nile.—A syndicate of American engineers and capitalists has been formed to utilise the water power in the North-East Fayoum, 30 miles south of Cairo. A branch of the great canal, the Bahr Jusuf, or river of Joseph, which now supplies the Fayoum with water, follows a deep ravine down to the Lake El-Qerun. The total difference between the Nile and the lake is about 220ft. It is calculated that by reopening the ancient canal, the Bahr Wardan, a fall can be obtained, without any considerable expanse for excavation, which would give an effective head of 160ft. The present flood discharge of the Bahr Jusuf is 2,863ft. per second, and the minimum discharge is 409ft. per second. The evaporating surface of

Digitized by Google

the lake, which is about 130ft. below the Mediterranean, is 78 square miles, and the evaporation is calculated at 98in. per year. There is no appreciable rainfall. This scheme, which is due to Mr. Cope-Whitehouse, forms part of his project for the utilisation of the reservoir basins—the Lulu and Raiyan—to the south. He proposes to supplement the minimum available summer supply by water drawn from his reservoirs, and to provide against the rise of the lake by diverting a portion of the discharge during the flood into the reservoirs. The chief engineer of the General Electric Company has submitted a proposal to the Egyptian Government through the Department of State in Washington. The large number of American tourists estimated as exceeding last year 2,500 persons—largely composed of men of business activity—has awakened interest in the United States as to a possible opening in Egypt for American capital and enterprise. It is proposed to establish a trolley line between Medinet-el-Fayoum and Gizeh-Cairo; but plans have also been drawn up for a new town to be called Azizieh, whose favourable sanitary conditions would, it is believed, speedily attract a population sufficient to make it one of the chief manufacturing centres of the world for cotton goods. French political support is being sought to overcome administrative inertia. This scheme does not seem to be entirely dissimilar to that of the French engineer which we described in our issue of June 21, p. 702.

South Staffordshire Institute.—Last week about twenty of the members of the South Staffordshire and East Worcestershire Institute of Mining Engineers paid a visit to the James Bridge steelworks of Messrs. F. H. Lloyd and Co., and the generating station of the South Staffordshire Tramway Company. The party assembled at the James Bridge railway station, and were thence personally conducted to the works of the first-named company by Mr. J. W. Hall and Mr. J. Heming, two of the directors, who, in the fullest manner, explained all the processes. Afterwards the party passed on in a special car to the generating station, under the guidance of Mr. A. Dickinson, engineer and manager. There they found three compound horizontal engines, with 10½in. high and 20in. low pressure cylinders, fitted with Corliss valves, steam being generated in three Lancashire boilers, 30ft. by 7ft. diameter, at 100 revolutions, and a boiler pressure of 120lb., each engine developing 125 i.h.p. There were also three dynamos, shunt wound, driven by cotton ropes, and at 450 revolutions giving an output of 260 amperes at 250 volts. Mr. Dickinson stated that his overhead electric traction system extended for eight miles, and he explained the arrangements which had been made to overcome objections and difficulties. The members expressed themselves much pleased with the completeness of the arrangements and the excellence of the appliances, and came to the conclusion, from statistics put before them, that that was the most economical system of traction yet devised. The party then went on to Walsall by special car placed at their disposal by the company, and sat down to tea at the George Hotel, Mr. H. C. Peake, the president, being in the chair, and Mr. A. Smith taking the vice-chair. After the meal the president announced that the members were invited to send their students to a meeting of the Federated Institute of Mining Engineers at Newcastle-on-Tyne on August 13, and, upon his proposition, Mr. Cooksey was added to the representatives of this institute on the council of the Federated Institute, the other representatives being the president and Mr. W. J. Haywood. Mr. W. H. Whitehouse and Mr. G. Rogers as auditors, and Mr. Scott and Mr. J. Hughes as scrutineers, were reappointed. The President proposed a vote of thanks to Mr. Hall and Mr. Heming for their kindness at the steelworks, and to Mr. Dickinsom for like kindness at the generating station, remarking on the interesting information which had been supplied by these gentlemen. He added that no plant could be laid out more efficiently and economically than that for the working of the electric system, all the details having been most carefully considered. Mr. Traglass (Messrs. Tangye's works), in seconding the proposition, said that, as regarded the electric installation, it seemed to be complete in every respect, and as compared with the American systems, the members were pleased to see that for simplicity and general arrangement the palm was entirely with the South Staffordshire Company. What they had seen at the generating station made them proud, and they felt that the greatest credit was due to Mr. Dickinson, both as a mechanical and an electrical engineer, for the manner in which he had carried out the work.

The Parker Conduit System.—We have received from Mr. J. E. Parker, of the Commercial Cable Company, New York, a description of an underground electric conduit system which he has invented. It consists of an iron conduit about 18in. deep by 15in. wide, with a flange on the underside 3in. wide or thereabouts. This conduit is set on a level bottom in the centre of the track and spiked to the cross-ties, the top being flush with the roadway. An iron cross-frame is inserted in the conduit at regular intervals and bolted to the sides. About 3in. from the bottom there is a bar ½in. thick, with holes in the centre, to which the shank of the insulator is bolted. The insulator has a channel across the top, about ¾in. deep, for the reception of the metal conductor. The conductor is of metal, 2in. or more deep, and thick enough to fit exactly into the channel at the top of the insulator. It is bevelled at the upper side so as to prevent the accumulation of dirt on its upper edge. The various sections of the conductor are connected together. The conductor projects about 1in. over the top of the insulator. The trolley guard consists of two bars of metal projecting from the bottom of the car, wide enough to ride easily in the road slot, connected together by a flat frame of metal, having a slot in the centre, in which is placed a wheel, which also runs in the roadway slot. The trolley guard performs three important functions. It clears away all obstacles from the slot, protects the trolley shaft from injury against the sides of the slot, and the wheel (which is an expandable wheel) presses against the sides of the slot, forms the earth or return current of the electricity after passing through the motor. The wheel is made of hard steel, so that it may not easily wear away, and the continual passing of the cars keeps the sides of the slot in good condition for making a good electrical contact. The trolley shaft is made of vulcanite or ebonite or some other suitable non-conductor. Its peculiar formation at the end insulates it. A simple mechanical device enables the motorman to reverse the position of the trolley so that the car can run in an opposite direction. The trolley shaft passes through the slot in the trolley guard, and as the slot in the trolley guard is of less width than the roadway slot, the trolley cannot possibly touch the side of the roadway slot. The end of the trolley nearest the conductor is hollow or horn-shaped, which insulates the trolley wheel, and effectually prevents any escape of the current. A wire through the centre of the trolley carries the current to the motor. A flanged wheel at the end of the trolley rides on the top of the conductor, and the trolley is kept in its place by a strong spring pressing it on the conductor. It is claimed that in consequence of the direct contact of the trench all along its length, and of the whole of the metal-work with the earth, that not only

Digitized by Google

is the contact for the return or earth current made with the greatest certainty, but any possible derangement of the conductor would be quite harmless both to person and property, because the conductor in that case would certainly touch some part of the metal-work of the conduit and make earth, thus preventing any effects of the derangement being felt even for 1in. from the spot where the contact takes place.

Metallic Sodium Produced by an Electrolytic Leak. — The Boston correspondent of the *Western Electrician* draws attention to a curious case in that town. It appears that the accidental sounding of an automatic fire-alarm in a Washington-street business house recently has brought to the attention of the Boston Board of Fire Underwriters a possible new source of danger from electric wires. According to the reports, for some time past a slight smoke has been seen issuing from the casement about the electric light wires in the basement of the Pray Building at the point where the wires enter from the street. When the insurance inspector arrived and the casement was removed it was found that a peculiar substance had accumulated about the wires, which, when moistened and struck with any hard substance, would give off flashes of fire. All around this point the woodwork was covered with a thick liquid, which had dried in places to a white substance resembling discoloured salt, and which was slippery to the touch and strongly corrosive. The wood itself was soft and badly discoloured. As this case was thought to be of considerable importance, it was placed in the hands of Messrs. Forbes and Glidden, electrical and chemical engineers, who immediately began an investigation. The deposit discovered about the wires proved upon analysis to be mainly metallic sodium. The substance is exceedingly combustible, and unites so readily with water that its presence in a damp cellar would be impossible under ordinary conditions. When it unites with water hydrogen gas is given off, and at the same time a considerable amount of heat is generated. Under certain conditions this heat would be sufficient to ignite the hydrogen gas. Hydrogen gas and air would form an explosive, and hence the greatest danger lies in the liability of an explosion if the gas should become ignited. The explanation of the appearance in a damp cellar of a substance so combustible and unstable in the presence of moisture as metallic sodium, is given as follows: The metallic sodium was undoubtedly the product of an electrolytic decomposition of impure sodium hydrate. This sodium hydrate came from the cement mortar used in laying the brick wall of the basement upon which the wires were supported. Some of the hydrate may possibly have worked its way through the wall from the cement used in the foundation of the paved street immediately adjacent. The electric current which caused the electrolytic action was due to a leak inside the casing from one of the mains. The leak was produced by the action of the sodium hydrate on the insulation covering the wires. This covering was what is known as weatherproof insulation, which consists of a cotton braiding covered with tar. Such a material is readily attacked by sodium hydrate, and its insulating properties destroyed. Moreover, the sodium hydrate itself furnishes a good path for the current when it has once penetrated the insulation. This case is especially interesting in connection with several of the explosions which have occurred in underground conduits, usually attributed to a leak in the gas-mains. In London it has recently been suggested that metallic sodium may possibly have something to do with these explosions. This, however, appears to be the first instance in which the appearance of metallic sodium has been proved and a complete explanation of an actual case given.

Prague Electrical Society.—At the last meeting of the Elektrotechnischer Verein in Prag, Prof. Dr. Puluj read a paper on "Magnetic Hysteresis and its Significance for the Construction of Dynamos and Transformers." In the armatures of continuous and alternating current machines, he said, and also in alternating-current transformers, the iron cores undergo a periodical remagnetisation, upon which a certain mechanical energy is expended and returned in heat. This magnetisation energy depends on the quality of the iron, and on the number of magnetic cycles or circuit processes, and amounts in a ton of soft wrought iron at 100 complete magnetic circuit processes per second to 17·6 h.p. In cast iron this expenditure of energy may be doubled, and in hard steel a still higher figure may be obtained. The author next discussed the methods by which the magnetisation energy of various classes of iron can be determined in a simple manner, and he explained how this energy is produced in consequence of the magnetic retardation or hysteresis of the iron, while the magnetism of the iron depends on the previous magnetic condition of the same. Dr. Puluj further demonstrated with the electrical lighting installation in the physical room of the society that with decreasing currents in the field magnets of the dynamo the excited magnetism, and, therefore, also the terminal pressure of the machine, are considerably greater than with increasing current-strength, which could be observed not only at the voltmeter, but likewise in the intensity of the light of the incandescent lamps. The author then communicated the results of many tests relative thereto, which had been made by himself and his scholars, and he remarked that hysteresis increases almost twofold the magnetisation energy in the iron wires experimented with if the latter are brought to a red heat in a charcoal fire or by means of alternating currents in the air. In conclusion, Dr. Puluj discussed the weakening of the magnetism which the iron bars suffer by division, as observed by Ewing, and showed how by using iron wire for armature cores, instead of sheet iron, the number of ampere windings necessary for the excitation of the field magnets must be substantially greater. Mr. Marschik then followed with a treatise on "The Effect of the Electric Current on the Carbonisation of Iron by Cementation." The author illustrated by diagrams the important part played by carbon in iron, and showed how the qualities of the metal altered with the carbon contents, thereby indicating the distinction between wrought iron, cast iron, and steel. He further showed that one kind of iron could easily be converted into another by introducing carbonising substances to iron poor in carbon; or, on the other hand, extracting carbon from a metal rich in that material by means of oxidising substances. Cementation is based on the first-named principle, which was carried out as early as the beginning of the previous century as follows: pure soft iron, of only 0·1 per cent. carbon, was embedded in charcoal and exposed to a clear red heat. In from 11 to 13 days the iron showed 1·2 per cent. of carbon, and after refining is transformed into an excellent steel. By using electricity the cementation process can be expedited in that, in addition to the heating, which makes the carbon molecules more easily movable, an electric current being conveyed to the iron through the charcoal facilitates the permeation of the carbon molecules into the interior of the iron. For this purpose a current of 55 amperes and seven volts is necessary, and, with a temperature of from 900deg. to 1,000deg. C., the process only lasts about three hours, the result being a steel layer of 10mm. (0·394in.), containing 1·2 per cent. of carbon.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

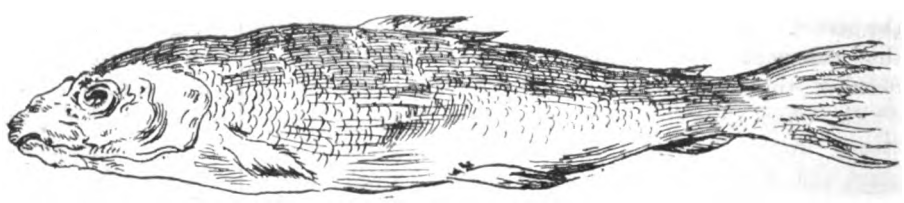
(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 74.)

JULY 6.

After viewing the distributing transformer stations at Thalkirchen, we took train again and returned to the suburban station to the south of Munich. There the electric power station for working the trams is situated, and the machinery in it was examined by the members. The buildings were not pretentious, but the plant installed was evidently well up to its work. Our party filled six cars arranged in three sets of two cars coupled together. The rear car in each set was an ordinary horse-car, having no motors on it. Then we started in series and raced back into Munich at an average speed of at least 12 miles per hour.

Primitive Grill.



The Renken.

The next visit was to the municipal electric lighting works. Mr. F. Uppenborn, the engineer of the station, was there to receive us and to explain the details of the various parts of the plant. The station is now in course of reconstruction and the water-power machinery is being greatly extended. The details of the engines, dynamos, and switchboards I hope to give fully later on from drawings which Mr. Oscar von Miller is sending to me. The type or general design of the station differs from any large English system I am aware of. The steam-engines supply power to a countershaft, from which the various dynamos are driven. A series of fast and loose pulleys are placed on this countershaft, acting as follow: Each dynamo is provided with a wide pulley, the face being equal to rather more than twice the belt width. Then on the countershaft two pulleys are provided, one fast and the other loose. When starting, the belt is on the loose pulley, and the two are forced together by levers till the friction is sufficient to start the loose pulley and the dynamo unloaded. Then when the normal speed is reached, the belt is moved over on to the fixed pulley by ordinary striking gear. To one end of this long countershaft a turbine is geared by the usual arrangement of mortice bevel wheel and pinion. At the other side provision is made for two more similar turbines, and the foundations are now ready to receive them. The works are situated on the south bank of the River Isar, in the midst of lovely gardens. The next item was a social *réunion* at the Isarluft Restaurant, but my appetite for imbibing information and liquid refreshment had departed, so I preferred a quiet evening with some friends at the hotel.

JULY 7.

This day was devoted to recreation rather than business, although those members who were sufficiently energetic paid a visit at 9 a.m. to the "central station of the central station which is not at the central station." I solved the above riddle and found that the electric lighting plant for supplying the central railway station was placed at a small depôt in the suburbs. After the works there had been inspected we went by special express train to Starnberg for the Starnberg See. The weather being propitious the scenery could be enjoyed to the full, although the distant Alps were at times obscured by mist. We took a "dampfschiff" to Schloss Berg, and then formed up in a straggling procession behind a local brass band, who played martial music to entice us along. Strolling along the path by the shores of the lake, we passed the memorial erected on the spot whence the mad King of Bavaria cast himself into the lake. There was no time allowed us to follow his example, although a swim in the clear waters would have been most refreshing. I was fortunate in securing Mr. T. W. W. Melhuish, of Vienna, as a companion during the day, and we had many notes to compare as to the old times when he superintended the lighting of the Inventions Exhibition at South Kensington for Messrs. Siemens Bros.

We took steamer again at the next landing-stage, and then had a most enjoyable sail round the "See," finally returning to Tutzing for luncheon. It seems that the lake is noted for a species of fish, called Renken, which is a great delicacy. The fish is of so delicate a constitution that it dies immediately it leaves the water when caught. The guide to the lake and district which was supplied us with our membership tickets was most useful on this occasion, and I wish the whole of the illustrations could be reproduced. After lunch, or rather between the courses, we had the usual speeches, which in this case had a personal tendency. Mr. Oscar von Miller, in proposing the health of Mr. Gisbert Kapp, referred in glowing terms to the work Mr. Kapp had done for the society during his first year of office, and congratulated him on being again in harness in the German Empire. Although I did not approve of the last sentiment, and wished we could have retained so able an engineer in England, I joined the troop of those anxious to clink glasses and "Prosit" with Mr. Kapp. After the tide swept back and we were again seated, other toasts were proposed; in fact, at one time two speakers wished to take the floor together, but the right of priority was amicably settled. After a pleasant homeward journey, first by steamer and then by rail, Munich was reached at about 8.30 p.m., and mutual farewells were exchanged. As I had to depart early the next day to visit various large engineering firms and central stations in Switzerland and Germany, I secured Mr. Kapp for a long chat lasting into the early hours of the morning. In conclusion of my Munich experiences I must add that the open welcome I received from all was most cordial, and never before have I made so many genial acquaintances in the short space of three days.

Renken Fishing.

Old Lake Dwellings.

My personal interviews with the various prominent

electrical engineers of Germany and Switzerland will be published in due order, commencing with the Munich engineer—Mr. Oscar von Miller.

THE DUBIAU TUBULAR PUMP SYSTEM FOR BOILERS.

At the recent meeting of the Verband Deutscher Elektrotechniker, Mr. Friederich Ross read a paper on the subject of the system for boiler circulation invented by M. Paul Dubiau, manager of the Association des Propriétaires d'Appareils à Vapeur du Sud-Est de la France. Rapid circulation is one of the advantages aimed at in water-tube boilers, but often this is not obtained in practice. The author stated that a satisfactory and simple means of attaining proper circulation was the tubular pump of Dubiau. The application to an ordinary Cornish boiler is shown in Fig. 1. Round the furnace is placed a mantle which reaches almost to the bottom of the boiler and is closed at the top by a lid, a number of tubes being brought through this lid, and the lower end of the tubes being cut in the shape of a whistle. On heating this boiler a second steam-chamber is at once formed over the furnace. As soon as the pressure in this is greater than the pressure in the upper chamber, in addition to the pressure of the water column, steam bubbles enter the tube and press the water contained in them ahead into the upper steam-chamber. The lower water surface then appears at the upper corner of the oblique surface of the tubes, that under the pressure of the water column then remains constantly filled with water, and each jet of steam empties the contents into the space above. In this manner there is at hand a means of circulating any given quantity of water by proper selection of the section and the number of these tubes, which work just like a pump. Naturally, a large quantity of the water runs back to the bottom of the mantle, and it is thus possible to obtain such rapidity of circulation that in an hour the quantity of the water contained in the boiler is passed from 60 to 100 times over the heating surfaces. With such a great circulation, the formation of adhering steam bubbles is prevented. In consequence also of the rapid motion, there is no chance of deposit being burned on in the most dangerous part—that is, where there are high temperatures of plates.

Another application of the system is shown in Fig. 2, in which an underlying boiler is combined with a tubular boiler and here a collection of Dubiau tubes is placed in the foremost part of the boiler. The water lifted is returned to the lower drum through the two connections between the upper and lower boilers.

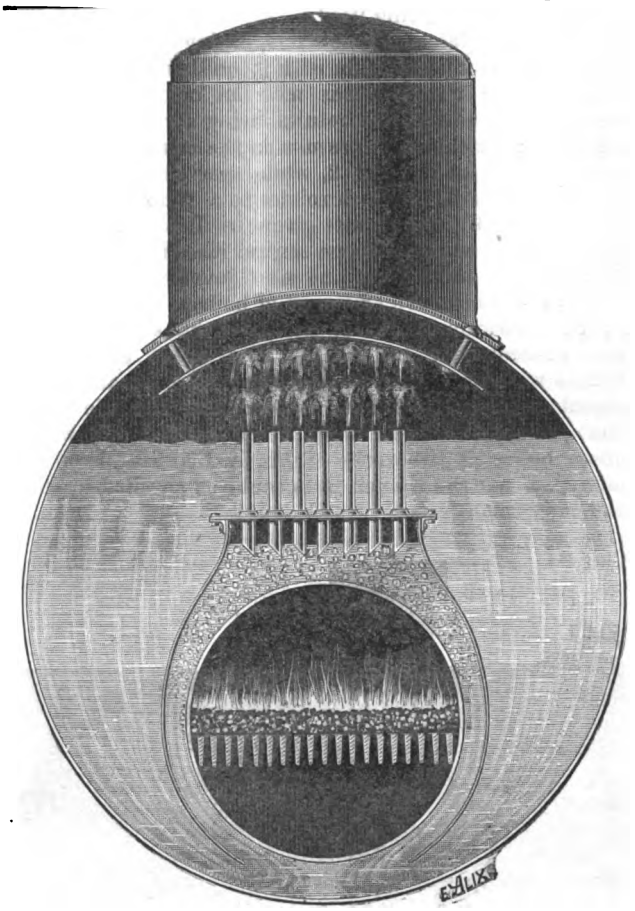

FIG. 1.

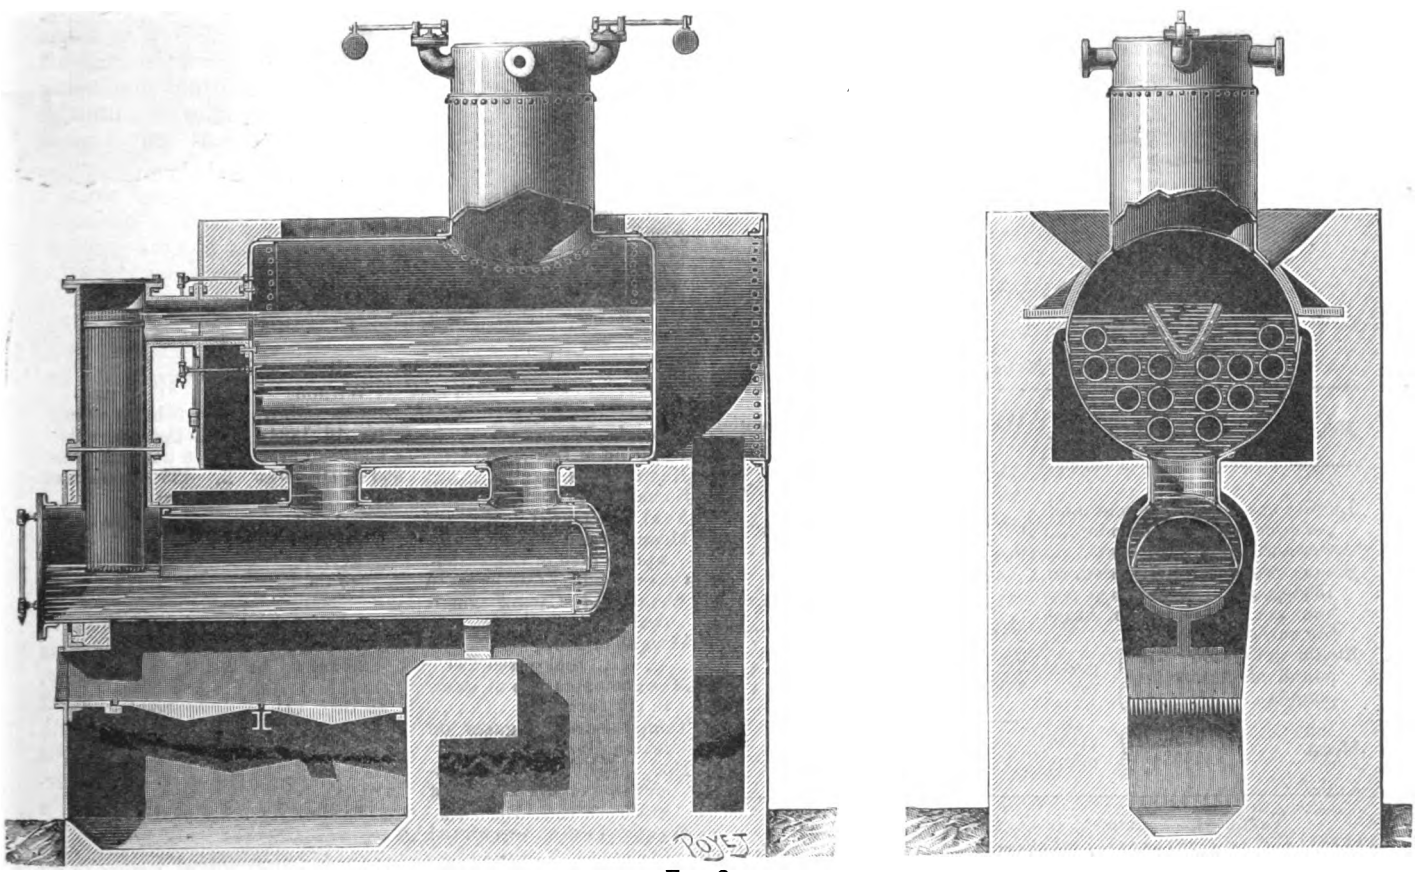

FIG. 2.

In Fig. 3 the Dubiau system is shown in connection with a tubular boiler, an application which can be readily understood. The water returns to the tubes nearest the furnace from the upper boiler by means of the ordinary return pipes.

Digitized by Google

The author stated that tests had been made which showed remarkable results from the increased circulation, on the average capacity of the boiler was doubled without any additional fuel being used.

The Dubiau system is a new one, dating from 1893, and experiments have been made with it on boilers of various types. One of the first was with an ordinary boiler by Menard, of Marseilles, the results being given in Table I. In Table II. are shown the results in the case of a combined boiler, as illustrated in Fig. 2, while specially good results appear in Table III., which relates to a tubular boiler, as shown in Fig. 3. Other tests given in Table IV. relate to a tubular boiler at the Dieppe central electric light station.

The author claimed that the new invention allowed of raising the quantitative efficiency of boilers by from 50 to 15 per cent. without inconvenience, and that smaller boilers could consequently be utilised and space economised. Deposits were prevented, temperatures were equalised, and unequal expansion of plates avoided, and the life of the boiler prolonged. Tests were being carried out with a Dubiau boiler at the works of Mr. E. Leinhass, Freiberg, Saxony, so that the French tests could be checked by independent German tests.

Gas coke burned	1,060lb.	1 930lb.
Ashes	88lb.	165lb.
Mean temperature of the gases over the furnace	987deg. C.	1,060deg. C.

LIGHTNING ARRESTERS, AND WHY THEY SOMETIMES FAIL.*

BY ALEXANDER JAY WURTS.

When the first telegraph lines were installed it was noticed that the instruments frequently became damaged during thunderstorms. The wires were charged with static electricity, which, instead of following many turns of wire through the instrument to earth, would puncture the insulation between consecutive convolutions and thus short-circuit the coils. Besides this damage to the instruments, it was noticed that the static charge would sometimes spring from the line, or other metallic parts of the circuit, to neighbouring conducting objects, such as nails, iron pipes, and the like. It was also noticed that, when discharge occurred in this manner, the instruments were not damaged. In other words, these neighbouring objects formed by-paths for the discharge, and, in a measure, offered protection to the instruments. As a consequence of such observation, artificial by-paths were constructed, which consisted of two metal electrodes, separated by a small air space. One of these electrodes was connected to the line, the other to earth; and thus the first "lightning arrester" was constructed.

It was then supposed that, when a line was provided with a "lightning arrester," the instruments would be "protected against lightning." The result, however, proved this conclusion to be erroneous. The discharges would sometimes pass to earth over the spark-gap of the lightning arrester, but not infrequently would quite ignore the arrester and, as before, puncture the insulating material of the instruments. In other words, the discharge was selective. The failure of the lightning arrester was a vexation; but at that time, owing to the small amount of apparatus in use, the damage reckoned in dollars and cents did not call for any special study of the reasons for the selective character of disruptive discharges. In these days, however, the vast amount of capital invested in electrical apparatus of various kinds, and the consequent increase annual loss directly due to these disruptive discharges, have called for a thorough investigation of the subject, and the designing of more efficient means of protection.

It is a very significant fact that overhead wires, after being subjected to the influence of thunderstorms, do not show the damage to insulation which one would reasonably expect to find had the wires been actually struck by the lightning discharge. It is not uncommon, however, to hear of wires being "struck by lightning"; in fact, linemen will frequently volunteer to point out the exact spot where the lightning entered the wire. But, so far as I have been able to learn, overhead wires are not struck by lightning. The points usually selected by lightning discharges are trees, lightning-rods, church steeples, tall chimneys, and the like. There seems to be no reason why lightning should strike a horizontal wire, especially when it is insulated from the earth.

Overhead wires may become charged in three ways and combinations of these—viz., by static induction from the clouds, by dynamic induction from a lightning discharge, and by conduction from the surrounding charged atmosphere. The writer inclines to the theory of conduction.

During thunderstorms, and in many instances during fair weather, the atmosphere becomes charged with electricity at a constantly increasing potential as we recede from the earth. At the top of Washington Monument, Washington, D.C., a potential of 3,000 volts has been measured during thunderstorms, and at the top of the Eiffel Tower a potential of 10,000 volts has been measured. Now, it is well known that lightning is oscillatory. The first oscillation, or discharge, makes a crack or hole through the atmosphere, and through this the succeeding oscillations take place. About 10 to 12 oscillations can be observed, and the time interval is reckoned at about ·00001 of a second. The lightning, therefore, being oscillatory and the atmosphere charged, if an overhead wire be charged by conduction from the atmosphere—that is, become electrically a portion of it—then, with every lightning discharge it would seem as though the potential of the atmosphere would sympathise with the oscillatory character of the lightning, and that the charge in the atmosphere would also oscillate and produce oscillations in overhead wires, and, in fact, in all metallic conductors, such as wire fences, rails, etc. The fact that wires become heavily charged during fair weather offers further evidence that they are charged by conduction from the surrounding charged atmosphere. In some instances lightning arresters have been known during perfectly fair weather to discharge overhead wires at the rate of 140 times a minute.

In any case, whatever the method of charging may be, the discharges from overhead wires seem to be oscillatory, and during thunderstorms they are in most cases simultaneous with lightning flashes.

If we raise one end of a trough of water and then quickly lower it, the water will quietly surge back and forth. If, when the water is returning, we again raise the same end of the trough, a wave will be started forward, which, meeting the returning wave, will combine or collide with it, causing a piling up of the water at that point. Further complications may be introduced by repeatedly, and at proper intervals, raising and lowering one end of the trough. If the crests of these waves be carefully examined, it will be noticed that they differ in height and are constantly shifting their positions.

During thunderstorms the static electricity in overhead conductors surges back and forth very much as the water in a trough, and the indications are that electric waves are set up which combine and interfere with each other in such a manner as to produce frequent and unequally distributed points of high and low pressure. The ends of wires are points of reflection, and at these points the pressure is always great. Whatever may be the true explanation of the apparent idiosyncrasies of disruptive discharges, it is, after all, with facts that we have to deal.

Referring to Fig. 1, let A A represent the terminals of a static induction machine, L a battery of six one-half gallon Leyden jars, B a spark-gap of $\frac{1}{32}$in., and C_1, C_2, etc., variable spark-gaps, and let the connections be as indicated. With discharges at B, discharges will also occur at one or more of the gaps, C_1, C_2, etc. When C_1, C_2, C_3 are equal, the discharges occur across these gaps indiscriminately. When discharge occurs over small gaps in the neighbourhood of C_1 or C_2, thread-like discharges are always noticed at Cn, and even when Cn is increased to $\frac{17}{32}$in. the thread-like discharge is still noticeable with every discharge at C_1 or C_2. If a large number of spark-gaps, varying among each other as much as 100 per cent., be distributed as C_1, C_2, C_3, etc., discharges will still occur indiscriminately, sometimes across a large gap, sometimes a small one, sometimes across three or four consecutive or widely distributed gaps. When C_1 is equal to $\frac{5}{32}$in., C_2 equal to $\frac{17}{32}$in., and placed two, three, or more feet away from C_1, and if C_3, C_4, etc., be omitted, then a discharge will occur at C_2 once in about 500 times without any discharge at C_1. These experiments demonstrate the selective character of the discharge. If, however, C_2 be increased to $\frac{18}{32}$in., the discharges will cease altogether at that point, and this last experiment indicates the limit of range over which selection may take place under the conditions given. But it is perfectly evident that with a large number of gaps, the probability of discharge across any one gap is very much less than if only two gaps were present. In other words, if C_1 represents a piece of apparatus which we desire to protect, the protection will be greater as we increase the number of spark-gaps, C_2, C_3, etc., but in no case can there be certainty of protection unless the gap, C_1, be relatively so large—or, more broadly speaking, unless the path, C_1, offer such a high resistance to the passage of disruptive discharges—as to place it beyond the limit of selection. The apparatus which we have used in the above experiments is different from that employed by Nature; the results, however, so far as my observations go, are identical, and the lesson to be learned is simple; it is this: the probability of damage to electrical apparatus connected to overhead wires is lessened as we increase the number of opportunities for discharge from the line.

In summing up thus far, we notice briefly that the line becomes charged, surgings are set up, there are points of reflection which are always points of great electrical strain,

* Lecture delivered before the Franklin Institute.

Digitized by Google

there are points along the line of varying intensity or tendency to discharge, these points are constantly shifting their positions, and spark-gap lightning arresters are used, to conduct disruptive discharges to earth.

The lightning arrester of to-day, as a protective device, differs from the lightning arrester of the early telegraph in detail only. A simple spark-gap, one terminal of which is connected to the line and the other to earth, is essentially the lightning arrester now in use. But, with the modern high-potential circuits, it is found that the dynamo current follows the static discharge across the spark-gap of the arrester, causing thereby a short-circuit or dangerous ground on the line. In order to avoid this difficulty, arc-rupturing devices are attached to the lightning arrester, which have for their function the immediate interruption of the dynamo current, without interfering with the further operation of the lightning arrester as a discharging device. "Automatic lightning arresters," as they are called, differ among one another in the various means adopted for rupturing the dynamo arc. But the arc-rupturing attachment has nothing whatever to do with the apparatus as a lightning arrester, so that although automatic lightning arresters vary in outward appearance, and are in general more cumbersome and expensive than the original simple spark-gap arrester, yet, as lightning arresters, they are nothing more than spark-gaps. Various lightning-arrester attachments have been designed for the automatic rupture of dynamo arcs, but owing to the very high potentials which are so often used, they are found to be not only undesirable, but inefficient, the lightning arresters being frequently destroyed by the vicious dynamo arc.

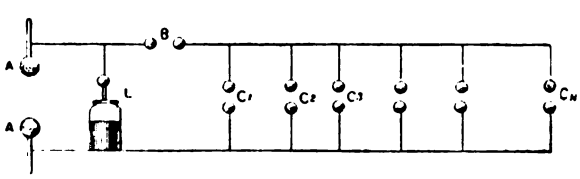

FIG 1.—Experiment with Line Arresters, Illustrating Selective Character of Discharge.

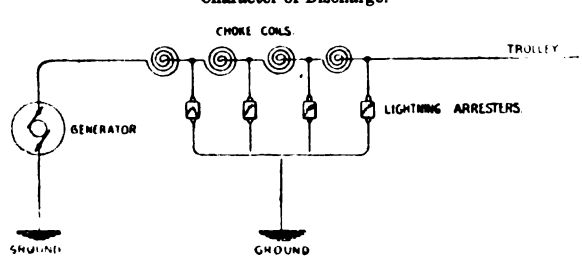

FIG. 2.—Four Choke Coils, with Lightning Arresters Intervening.

In practice, however, complaints are not so much that lightning arresters are destroyed as that they "fail to protect." It is not unusual to see several different kinds of lightning arresters in a single station, which have evidently been installed with the idea of determining which one of them would prove the most efficient. But such experiments have met with disappointment, for the reason that sometimes one lightning arrester, and sometimes another, would receive the discharge, and the selective character of disruptive discharges was not understood. The failure of lightning arresters is not due to the particular kind of lightning arrester, or to the patent under which it is manufactured; it is due largely to the peculiar conditions with which it has to contend—namely, that the discharge is selective, and that, in order to protect apparatus, means must be taken to control these selections, or, at least, to provide so many paths to earth that the probable selection will be one of the many paths provided. In other words, lightning arresters do not "protect"; they simply offer opportunities for discharge. These opportunities may or may not be embraced, according to circumstances. But the failure of lightning arresters is not altogether due to the peculiar conditions already referred to. Poor ground connection, inductive resistance in the ground circuit, defective insulation in the apparatus to be protected, and a general misunderstanding of the subject, are not infrequently the cause of serious losses which might otherwise have been avoided.

We have noticed that lightning arresters do not "protect," that they simply offer opportunities for discharge. We have also noticed that discharges do not pass readily through coils of wire: coils therefore protect. Properly-constructed choke coils, connected in the circuit, offer a high resistance to the passage of disruptive discharges, and when used in connection with lightning arresters, the combination offers a very reliable means of protecting well-insulated apparatus against lightning. Laboratory experiments, together with tests made under actual working conditions, indicate the advisability of using four choke coils in series, in each wire, with four lightning arresters intervening, as shown in Fig. 2. This arrangement is more particularly suitable for the protection of station apparatus. Coils can, however, be used to advantage on the line for the protection of the more expensive translating devices.

The general construction of a choke coil is a matter of considerable importance. A flat spiral possesses some advantages over the helix, but for practical purposes these hardly compensate for the lower cost of the latter, which for best results should be wound over a wooden or other non-conducting core. Metal cores and cases should be avoided, because the induced currents in these parts would lower the choking effect of the coils. The number of turns which can be used to advantage is limited. It is found by experiment that with given conditions the choking effect increases with the number of turns up to a well-defined critical point, after which additional turns fail to have any appreciable effect. It is probable that these critical points vary with the amount of electricity discharged—that is, for heavy discharges the critical point for maximum choking effect would embrace a larger number of turns than would smaller discharges, and the choking effect for a given number of turns within the critical point would also be greater for heavy than for small discharges. For practical purposes, the writer recommends from 40ft. to 50ft. of wire wound either into a flat spiral having an internal diameter of 3in., or into a 3in. helix with a single layer.

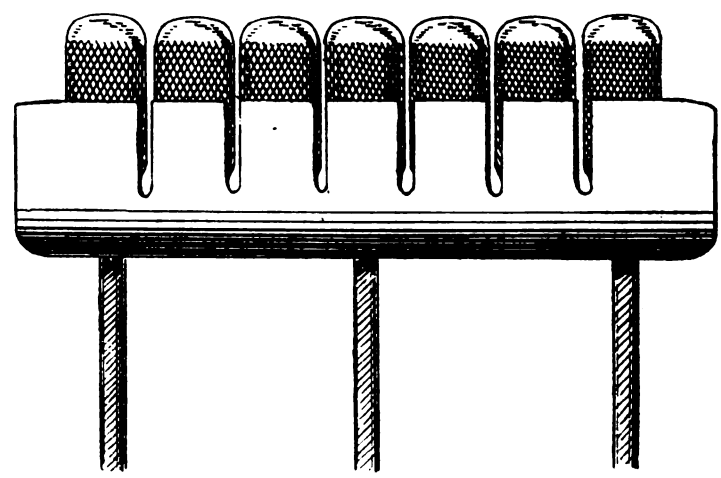

FIG. 3.—Double-Pole Non-Arcing Metal Line Arrester.

Summing up once more, we note that wires become charged, that lightning arresters offer opportunities for discharge, and that coils protect. Bearing in mind these three points, let us note that, with the extensive systems of electric light and power distribution now in use, it would be quite impracticable to instal the above-described system of choke coils and lightning arresters for the protection of each separate piece of apparatus. The first cost of such an installation would be prohibitory. It is evident, therefore, that the protection of line apparatus with choke coils being excluded there remains but one alternative—namely, that of providing such a large number of opportunities for discharge, distributed over the entire system, that the selection of the discharge will be one or more of the paths provided for it. In other words, line arresters connected at frequent intervals offer the only practical method of protecting widely distributed apparatus. But, in order that such an installation may prove satisfactory from a commercial as well as an operative standpoint, the arresters must be cheap, simple, free from moving parts,

Digitized by Google

and perfectly reliable without the necessity of regular inspection.

Realising that these points were not covered by any one of the many automatic lightning arresters which had already been devised, I undertook to simplify the problem, and in my early experiments proposed to equip the lines of electric systems with a multiplicity of spark-gaps, and at the station to provide an automatic circuit opening-and-closing device, which upon the formation of a short-circuit across one or more of the spark-gaps on the line would instantly open and then immediately close. While experimenting with this system, I discovered that if the electrodes of a lightning arrester were made of zinc, the short-circuiting arc, which had heretofore threatened the life of the lightning arrester, absolutely failed to be maintained. In other words, zinc proved to be what is now commonly known as one of the "non-arcing" metals. Subsequent investigation disclosed the fact that there were four other metals which exhibited similar characteristics—namely, bismuth, antimony, cadmium, and mercury.*

The discovery of the non-arcing metals at once solved the problem of a lightning arrester adapted to the requirements of alternating-current circuits, and which would meet the conditions already enumerated.

The non-arcing metal lightning arrester, which is illustrated in Fig. 3, consists, as will be seen, of seven non-arcing metal cylinders, insulated from each other, each 1½in. long and ⅝in. in diameter. When installed, the two outer cylinders are connected to either leg of an alternating-current circuit and the central cylinder to earth,

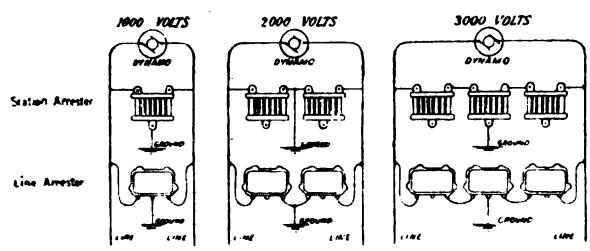

FIG. 4.—Diagrams for Lightning Arrester Connections on Circuits of Different Potentials.

thus forming a double-pole lightning arrester. In practice these are manufactured in units for 1,000 volts, so that for 2,000 volts two are connected in series, for 3,000 volts three are connected in series. The diagrams in Fig. 4 indicate the connections for each potential. There are many thousands of these lightning arresters in actual service, and the experience of three years has fully demonstrated that they are perfectly reliable without the necessity of regular inspection. The simplicity of the device is at once apparent, and the cost to the user is a mere fraction of what was formerly demanded for the best types of automatic lightning arresters. It will thus be seen that, at least for alternating-current circuits, the requirements of a commercially serviceable line lightning arrester have been fully met.

The success of the non-arcing metal lightning arrester was such that I was induced to make further investigations as to the possibility of constructing an equally simple and efficient device for use on direct-current circuits. In view of the many experiments which I had made with almost every kind and combination of the ordinary metals, I had become convinced that I should not be able to construct a non-arcing lightning arrester for direct-current circuits which would derive its non-arcing property from the nature of the material of the electrodes, as is the case with the non-arcing metal lightning arrester. Accordingly I directed my attention to the possible suppression of the dynamo arc by virtue of the construction or relation of the parts.

I had already observed the remarkable ease with which disruptive discharges strike over insulating surfaces, as compared to the difficulty with which they ordinarily pierce the air. For example, disruptive discharges will strike over a glass surface, between two electrodes placed 8in. apart, rather than pierce the air between electrodes placed 1in. apart and shunting the electrodes in contact with the glass. If ground glass be used and a pencil mark be drawn between the widely separated electrodes, the ratio between the distances over the glass and through the air is increased. While endeavouring to avail myself of this principle of "surface discharge," as I have called it, it occurred to me that a dynamo arc, in order to exist, must be fed by the vapours of its electrodes, and that if such vapours could be suppressed, or if their formation could be avoided, an arc could not possibly exist. Placing these two ideas together—namely, "surface discharge" and "suppression of the vapours"—I at once had the fundamental principles necessary for the construction of what has since proved to be a most simple and efficient non-arcing lightning arrester for direct-current circuits.

In the first experiments which led to a practical adaptation of these ideas to the construction of a lightning arrester, I placed two aluminium-foil terminals between the surfaces of two small blocks of marble, the surfaces of which had been carefully ground, and on one of which I had drawn a pencil mark which should bridge the distance between the foil electrodes. At first these electrodes were placed about 2in. apart, the two blocks of marble were firmly bound together with twine, the terminals were connected to the terminals of a 500-volt direct-current generator, and disruptive discharges were then caused to pass from one foil terminal to the other, between the marble blocks and over the pencil mark. It will at once be seen that the function of one of these marble blocks was to furnish a surface discharge plane, that the pencil mark was to further facilitate the passage of the disruptive discharge, and that the function of the second block, which was firmly bound to the first, was to suppress the formation of vapours, which would otherwise serve to establish a short-circuit under the conditions of the test. No arc being formed, the terminal foils were brought successively nearer to each other, until, finally, when the discharge plane had been shortened to ¼in., a short circuit was established.

Without entering into the details of subsequent experiments leading to the practical construction of a commercial lightning arrester, it may briefly be stated that in the final form wood, having been found more durable, has been substituted for marble, and, in place of the pencil marks, shallow grooves are burned longitudinally between the terminal electrodes, which are placed ⅝in. apart. While submitting this form of lightning arrester to long-continued tests with disruptive discharges, it was found that there was a gradual wearing away of the wood fibre, which eventually ended in the formation of a cavity in which vapours formed in sufficient quantity to establish a dynamo short-circuit. The wearing away of the fibre seemed to be due to the fact that no special vent, or opportunity for displacement, was provided for the disruptive discharge. This evil was quickly cured by slotting the upper block at right angles to the charred grooves in such a manner as to open up the grooves or discharge plane to the air, without, however, uncovering the electrodes.

It will now be proper to notice the distinctive features of the two non-arcing lightning arresters which have been described. The non-arcing metal lightning arrester is non-arcing by virtue of the material of its electrodes, and though "non-arcing," nevertheless allows of the dynamo short-circuit. This is, however, so quickly interrupted, probably by virtue of non-conducting vapours which form between the electrodes during the first rush of current, that no appreciable burning or damage to the electrodes can be noticed, and the melting of fuses and consequent interruption to the service are entirely avoided. On the other hand, the non-arcing lightning arrester for direct-current circuits is "non-arcing" by virtue of its construction, and more than this, is, strictly speaking, a discriminating lightning arrester, in that it allows disruptive discharges to pass freely without allowing any dynamo current at all to follow. This last feature is one which has enabled me to make some interesting investigations regarding the relative volume of discharges from overhead wires during thunderstorms.

* A full description of the researches and experiments which led to the discovery of the non-arcing metals is given in the *Transactions* of the American Institute of Electrical Engineers for March 15, 1892.

Digitized by Google

While carrying on a series of experiments in Colorado during the summer of 1893 I connected in series with a number of these discriminating lightning arresters small spark-gaps, into which I inserted pieces of tissue paper, which were intended to act as tell-tales, and which, by the holes punctured by the discharges, gave me some record of what was going on. Some of these tell-tale papers are shown in Fig. 5. It will thus be seen that, although the discharges which caused these holes were larger than is ordinarily obtained with a battery of Leyden jars, they are not to be compared with the holes which one would expect from the lightning flashes which are so often said to "strike the lines." The fact that these tell-tale papers were not burned is sufficient evidence that the dynamo current did not follow the discharge.

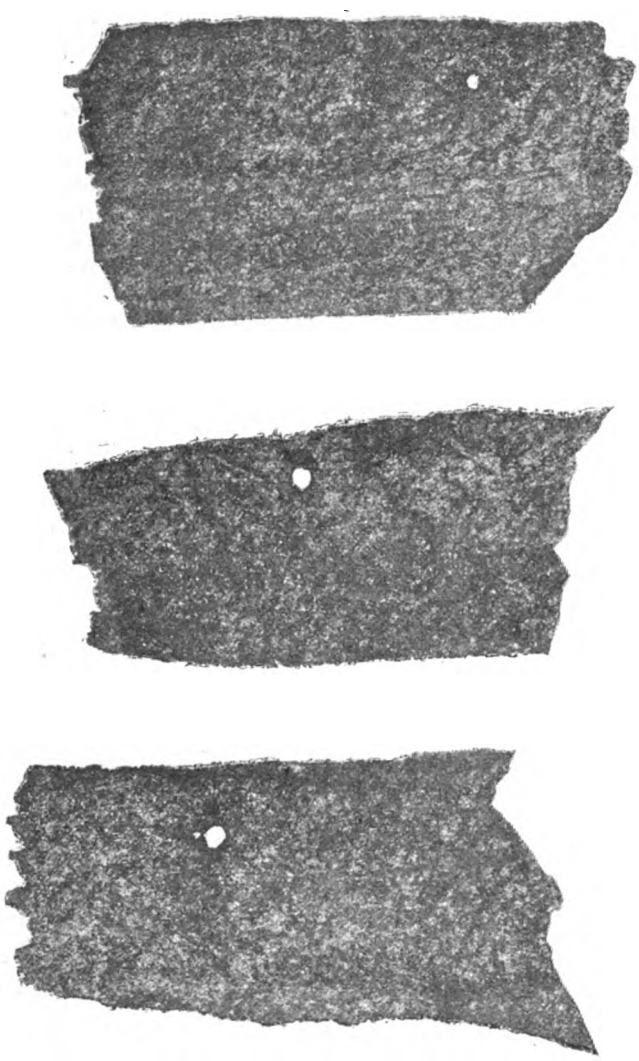

FIG. 5.—Tell-tale Papers.

There is, however, another side to this matter of protection against lightning—one which has been little discussed, and which is almost invariably overlooked by those to whom interruptions due to lightning are a matter of vital importance. I refer to the insulation of the apparatus to be protected. When a lightning arrester "fails to protect" it is condemned, the general opinion being that the failure is due to some inherent fault in the lightning arrester. But we have already learned that a lightning arrester is nothing more than a spark-gap. It would be difficult, then, to conceive of anything fundamentally wrong with a lightning arrester, so far as offering an opportunity for discharge is concerned. We have also learned that disruptive discharges do not always embrace the opportunity for discharge which is offered by a spark-gap lightning arrester. This circumstance, a very frequently occurring one, explains why lightning arresters sometimes fail. Another and all too frequent cause is defective or improperly applied insulating material. In a certain sense a lightning arrester is a safety valve. One would not expect to protect a defective or weak boiler with a safety valve set to blow at or near the bursting strain of the boiler; no more should we expect a spark-gap lightning arrester to protect weak or defective insulation.

Defective insulation results either from weak insulating material, or a faulty application of the insulating material. Generally good insulating material is used. Faulty application may result in two ways: (*a*) through improper design; (*b*) through carelessness or ignorance. Examples under (*a*) are: (1) exposed surfaces offering opportunities for "surface discharge," and this is not an infrequent occurrence in connection with insulating materials which would otherwise stand very high voltages; and (2) insufficient allowance for a proper margin of safety. The effects of rough handling, heat and cold, damp and dry atmospheres, dirt and grit (this latter having a particular attraction for electrical apparatus, etc.), demand a margin of safety which is not always appreciated even by the designer. Under (*b*) might be mentioned a long list of details, such as bruises, cracks, pinholes, cuts, open joints, bits of metal embedded in the insulation, sharp corners, etc., which will tend to lower the insulation strength 50, 75, or even 100 per cent. And at this point it should be observed that the weakest point in the insulation of a given piece of apparatus (it may be a pinhole or minute crack invisible to the naked eye) is a measure of its insulation strength.

Repair work in shops of local electric light and power companies is liable to be more or less defective, and but few such companies are provided with testing sets. Repaired armatures and converters are placed in service, and might stand indefinitely the normal E.M.F. of the circuit to which they are connected, but field discharges, lightning, rise of potential, and proximity to other circuits carrying high potentials demand a margin of safety which cannot be assured unless the insulation be actually tested with an E.M.F. from four to six times the normal.

But, even though the insulation of apparatus be perfect and have its proper margin of safety when installed, deterioration may nevertheless occur from various causes, principal among which would be moisture and overheating. In general, it may be stated that if we undertake by means of spark-gaps to provide absolute protection against static disruptive discharges, the insulation strength must bear such a relation to the spark-gaps as to place it beyond the limit of selection. Ordinarily, however, absolute conditions do not occur in practice; we can but approximate to them, and then philosophically accept a reasonable percentage of failures as inevitable.

The failure of lightning arresters is too often due to careless installation. It may be instructive to note several examples:

(1) One plant is reported as having, for better protection, connected two arresters in series. This was probably done with the idea that if a little was good more would be better.

(2) A large bank of station arresters was grounded to an iron bolt about 2ft. long, driven into dry sand.

(3) Line arresters were grounded by pushing the ground wires into the earth.

(4) Line arresters were grounded on iron poles, which were themselves set in Portland cement.

(5) An annual inspection of automatic lightning arresters developed the fact that the arresters were nearly all burned out—in other words, that the line was left unprotected.

(6) The ground plate of a bank of arresters was thrown into a neighbouring stream, which subsequently changed its course, leaving the ground plate high and dry.

(7) The ground plate of a bank of station arresters was laid on the rock bottom of a neighbouring stream.

(8) In a large number of cases a portion of the ground wire is wound into a fancy coil (choke coil). And the list might be indefinitely extended, each such case forming a source of complaint that the arresters "fail to protect"; but when these curious mistakes are located and properly remedied the complaints cease.

Summary.—Overhead wires become charged. They are discharged through lightning arresters, which are spark-gaps. Shifting points of high and low pressure are formed

Digitized by Google

along the line, so that the discharge does not necessarily occur over the shortest or easiest path—that is, the discharge is selective. Lightning arresters offer opportunities for discharge. Coils protect. A liberal distribution of line arresters offers the only practical means of protecting widely distributed apparatus.

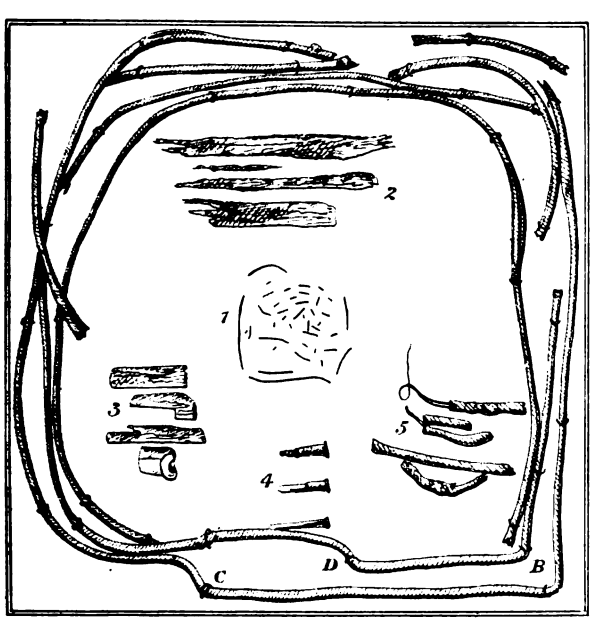
Lightning arresters fail to "protect"; first, because of the shifting high and low pressure points, or, in other words, for lack of a sufficient number of line arresters; second, because insulation is defective; and, third, because lightning arresters are not properly installed.

A SINGULAR EFFECT OF LIGHTNING STROKE IN CHICAGO.*

BY W. M. STING.

On September 7, lightning struck the factory building of the Illinois Industrial Home for the Blind. But slight damage was done to the building, though some of the effects on the electric light wires were most singular.

The writer is indebted for the facts here noted to Mr. Thomas Appleton, civil engineer, of Chicago, who was the superintendent of construction for the building. The Industrial Home is located on Douglas Boulevard, Chicago, the factory building being near the C. B. and Q. tracks. In his report to the Board of Trustees, Mr. Appleton states: "During the storm of last Friday night the chimney of



Effect of Lightning Stroke on Interior Wiring.

the factory was struck by lightning, and about 6ft. of the south side of the chimney knocked down. The lightning also entered the room in the south-east corner of the upper floor, and destroyed some 50ft. of insulated wire, one drop cord and pendant, and the switchbox. A large sliver was knocked off from the lower side of one of the roof beams, and it was a wonder the roof was not set on fire. Probably the whitewashing of the beam hindered the kindling of a fire at this point."

The roof beams were anchored by iron plates spiked on to the sides of the beams and extending through the wall, with large cast-iron washers outside the brick. The electric light wiring was open, cleated work, and was carried around the beams near the anchor plates. The lightning apparently struck an anchor plate and passed from this to the wiring. It knocked a near-by switchbox to pieces, breaking the porcelain fixtures and burning the screws. The upper screw of group 4 in the illustration shows the iron near the end melted out, leaving only the thread, like a spiral spring. Group 3 is a splintered oak cleat, while group 2 shows some slivers knocked off the beam.

The effect of the lightning on the wires is the singular part of the case. The outside diameter of the wire was $\frac{3}{16}$in., the conductor being No. 14 A.W.G. Around the conductor was a soft layer of white rubber, over this a layer of black rubber, which was covered with the usual protecting layer of braid. The insulation was heavily coated with compound and finishing varnish. About 10ft. of the insulation is shown in the illustration, for it is only a tube, the wire for the most part having disappeared, except between the letters B, C, and D. Group 5 shows damaged pieces with the conductor present, though badly burned. The outside of the insulation in many places plainly shows the effect of heat; the varnish has disappeared and most of the compound melted out. At irregular intervals there are openings or ruptures. A few feet was split open and the rubber core found intact, and only in a few places did it show traces of burning. There were scarcely any traces of copper markings that would indicate the wire had been vaporised. After the accident the conductor was found scattered about the floor. For the most part, the pieces were from $\frac{1}{4}$in. to $\frac{3}{4}$in. in length and quite regular. Group 1 shows a number of these pieces. The wire seems to have been literally shot out from the insulation as from a gun. The uniformity of length of these pieces is significant. When a long piece of fuse wire is blown it invariably breaks into a number of pieces of quite uniform length. The two cases seem quite similar and indicate in a manner some form of rhythmic action. The faces of the ends in both cases are square and crystalline. This would suggest that the copper conductor was fused internally, but cooled rapidly when exposed to the air. Only a few of the pieces are pitted and badly burned. An occasional piece of wire was found in the inner tube, but they were of uniform length with those that had been ejected.

* From the *Electrical Engineer* (New York).

FRANKFORT CENTRAL ELECTRIC SUPPLY STATION.

The following is a list of charges for current made by the Frankfort-on-Maine Central Electric Supply Station:

Current for electric lighting purposes, 80 pfennige, or 9½d., per kilowatt-hour, with the following discounts:

5	per cent.	for a consumption of	over	300	hours.	
10	,,	,,	,,	,,	500	,,
15	,,	,,	,,	,,	750	,,
20	,,	,,	,,	,,	1,000	,,
25	,,	,,	,,	,,	1,500	,,
30	,,	,,	,,	,,	2,000	,,

The number of hours of consumption being taken by a division of the power required by the lamps installed into the number of killowatt-hours of consumption.

Current for electric motors (except those used for driving dynamos or serving batteries for lighting purposes) for heating and for electro-chemistry: 20 pfennige, or 2⅖d., per kilowatt-hour, with a discount on the total consumption.

5	per cent.	for a period of	running	of	over	750 hours.
10	,,	,,	,,	,,	1,000	,,
15	,,	,,	,,	,,	1,500	,,
20	,,	,,	,,	,,	2,000	,,
25	,,	,,	,,	,,	2,500	,,

The number of running hours being taken by the division of the number of kilowatts required for the normal supply of the motors by the number of kilowatts used in the year by the consumers.

The meters required are hired to the consumers at the following rates, and remain the property of the electric supply station. The cost of maintenance and repairs is borne by the station, provided the damage has not been caused by the hirer. The yearly rental is—

For meters up to	0·5	kilowatts	.....	15s.
,, ,,	1·0	,,	.....	20s.
,, ,,	2·0	,,	.....	30s.
,, ,,	4·0	,,	.....	40s.
,, ,,	10·0	,,	.....	50s.
,, ,,	20·0	,,	and over	60s.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank.'*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

CENTRAL-STATION FINANCE.

Anyone reading the technical and non-technical Press systematically with the idea of ascertaining the true financial positions of the various electric light stations in this country, will be considerably mystified unless he has unlimited powers of supplying lacking information. He will cull from some after-dinner speech of a prominent member of the profession that a total cost for generation of three-pence per unit is rarely exceeded in well-designed electric light stations of the present day. Next, he will find that at Frankfort the charge per unit is only to be three-farthings for certain purposes. Then, carrying him still further in the rapid descent of prices, he will learn that the Niagara Power Company only charge one-eighth of a penny per unit. We can imagine a gentleman, after the course of reading referred to, saying, "Well, electricity is in its infancy in England, and the selling price here will fall rapidly." The next day, perhaps, he finds that some company which should be able to generate current cheaply is losing money when selling at eightpence per unit. His natural assumption is that the engineer and all concerned with the said supply are at fault. Roughly, we would divide all electric supply concerns into two classes, the first of which we are thankful to be mostly concerned with in England—*i.e.*, those electric lighting works started with the object of supplying light and power, and looking to the revenue derived from such sources to pay a reasonable interest on the money invested. The second class includes all companies started for either promotion-money or for ulterior purposes, such as land speculation. This latter class we do not consider in the following remarks, as their prices are not regulated by the considerations of supply and demand. In dealing with the first division, we consider that a too close attention to the average cost of production is apt to lead to a short-sighted, hampering policy. Mr. G. J. Melms, the engineer of the Frankfort station, in a letter we publish in this issue, touches on the question from the commercial aspect, and we endorse his method of reasoning. The average cost per unit does not in any way represent the cost per unit of generation at an average period. During the heavy lighting periods in the winter, ranging, say, from 4 to 10 p.m., the cost of generation is exceedingly small when the large outputs are considered. At other periods of the day, and almost all day in the summer, the actual cost of production per unit exceeds the price obtained from the consumer. We should proceed to reorganise the prime-cost sheets as follows: Assuming the primary object of the station is lighting, and that the great bulk of the plant is only running during the hours of maximum lighting, the capital charges and a large percentage of the managerial charges should fall on the lighting period. The income from the units sold for lighting purposes can, at least in England, always bear these charges. Then we have left the unprofitable periods, amounting to at least three-quarters of the total hours in the year. During this time the engines, boilers, and general machinery have to be

Digitized by Google

kept running to supply next to no load, and the wages' bill and depreciation are almost as heavy as when all the plant is at work. The coal consumed per unit supplied is enormously higher than any published figures, and the engines are apt to give more trouble when running light. Then our Frankfort correspondent steps in and says, Supply at cost price of labour and coal during this period if you can get a large consumer. The low figure mentioned in connection with his station was for a 120-h.p. motor to be run almost continuously, which mean an income of about one thousand eight hundred pounds per annum. The consumer thus gets his power at the not unreasonable figure of fifteen pounds per horse-power. The station engineer will in this way practically provide for the light-load coal bill. It looks somewhat like making money by selling large quantities of electricity at a loss if the average prime cost is considered, but it is in our opinion a sound business policy. The other smaller motors, of course, would not get the supply at such advantageous terms. Another vexed point with station engineers is that of street-lighting. It seems to be an acknowledged custom amongst technical advisers to corporations to insist that arc lamps shall be supplied at considerably less than cost price. We suppose the City of London Company set the example by openly accepting street-lighting at non-paying prices. Here there was an object, and they succeeded in getting a concession entitling them to supply the rich City consumers at eightpence per unit. The profit on the private consumers has already swamped the public lighting loss, but in provincial towns this is often not the case. When the electricity works are owned by the corporation, we fail to see why the electric lighting committee should not charge the full cost of production, plus interest on capital, to the street-lighting officials. The present policy simply falsifies the balance-sheet of the electrical engineer in charge, and circulates the idea that the electric department is losing money. This is done in order that the street-lighting bill may be kept low. In conclusion, we would again advise those engineers and committees who wish to make their electric light stations more successful, that they should supply power to consumers requiring the same continuously at a price at which it will supersede other prime movers of moderate powers.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COST OF POWER.

SIR,—In your editorial of July 5, commenting upon the cost of power at Niagara Falls, you make the statement that the capital charges alone would appear to prohibit a profit when power is supplied at ⅛d. per kilowatt-hour. Your assumptions are unquestionably right if the Niagara Falls Power Company supplies all of its power at this rate, a rate which would soon place any ordinary company in the hands of a receiver. However, even with as low a price as ⅛d. per kilowatt-hour, the Niagara Falls Power Company may reap advantage provided the consumer is not permitted to use power at the time when the maximum lighting load is upon the central station.

The cost of producing a kilowatt-hour in a station that is in operation 24 hours per day should, in my opinion, be divided into two parts: (1) interest on cost of plant, etc., depreciation, salaries, and that portion of the labour, water, and coal used during the time of maximum load for lighting purposes, or say, in round figures, four hours per day; (2) the cost of coal, water, and labour used during the balance of the day, or 20 hours. In this way, the cost per kilowatt-hour under the conditions just mentioned depends upon the time of the day when it is produced; in Frankfort the cost per kilowatt-hour in case 1 is about three to four times as great as in case 2, due to the establishment charges being debited to the lighting period only.

For lighting purposes, the Frankfort station charges at the rate of ·80M. (9·6d.) per kilowatt-hour, with discounts ranging from 5 per cent. to 30 per cent., according to the lamp-hours used during the year. The rate for power is ·20M. (2·4d.) per kilowatt-hour, with discounts ranging from 5 per cent. to 25 per cent., according to the number of kilowatt-hours consumed per annum.

We are also prepared to furnish power in large quantities—that is to say, 1,000,000 kilowatt-hours or more per annum—at the rate of ·065M. (·77d.) per kilowatt-hour, under the following conditions. The current is supplied during the year, 24 hours per day, except during the months of November, December, and January, when, at the option of the central station, the current can be cut off during the time of maximum load—that is, from 4 p.m. to 8 p.m. At this rate, ·065M. per kilowatt-hour, we still have a profit (assuming, of course, that the cost is figured on the basis, case 2), and the advantage of having a constant load upon the station.

The Niagara Power Company offered the city of Buffalo the horse-power hour per annum (24-hour power) for £4, and the arc light per annum at the rate of £10. The difference in these prices perhaps indicates that the Niagara Company is figuring on some such basis as above mentioned. It would be interesting to learn whether the exceptional price of ⅛d. was not given for other considerations—in the case of the aluminium works, as a consumer of an otherwise waste product; in the case of the city of Buffalo, as a consideration for receiving a valuable franchise.—

Yours, etc.,
G. J. MELMS,
Director, Städtisches Elektricitätswerk.

Frankfort-on-Main, July 17, 1895.

[We print the Frankfort schedule of prices for electric lighting and power in another column.—ED. *E. E.*]

THE CENTRAL LONDON RAILWAY.

An undertaking which will give employment to large numbers of all classes who occupy themselves with railway construction is on the point of being commenced. It is an underground line, which will run from Shepherds Bush, where Goldhawk-road and Uxbridge-road meet, to Liverpool-street; and it will be known as the Central London Railway. It is to be made on the Greathead system. Electricity is to be the motive power.

A Bill for the construction of an underground railway from Oxford street to the City was brought in as far back as 1864, but was thrown out by a joint committee of the two Houses of Parliament. It would naturally have been made, like the Metropolitan Railway, on the "cut and cover" system; and it was to have passed under Oxford-street and Holborn. A similar Bill, for a railway from the Marble Arch to Whitechapel, was brought forward in 1872. This was rejected because the committee did not consider that it would be possible to raise the capital, which was put at £6,400,000. In 1890 an electric railway from the City to Queen's-road, Bayswater, was proposed, but the Bill did not pass the Upper House. However, in 1891, the Central London Railway Act, for a line from Shepherds Bush to Cornhill, became law; and in 1892 an additional Act with the same title authorised the extension of the line to Liverpool-street, and the construction of an underground station in front of the Royal Exchange.

Digitized by Google

The line will be 6½ miles long, and will run at a depth of about 80ft. below the surface of the ground. There will be 14 stations, at each of which cylinders will be sunk, through which the spoil can be removed and the cast-iron segments for the cylinders lowered; so that, if necessary, 26 shields could be used, and work carried on at 26 faces simultaneously. Unfortunately, the spoil will all have to be removed by carts, water carriage, which is of such immense advantage to the contractors of the Waterloo and City Railway, not being available. Borings have shown that the work will be entirely in the London clay, and it is not likely that compressed air will be required anywhere. There will be separate tubes for the up and down lines; these will be 11ft. 6in. diameter, which is a mean between the sizes of the City and South London and the Waterloo, the former being 10ft. 6in. diameter and the latter varying from 12ft. 1¾in. to 12ft. 9in. In gradients the new line will have the advantage over its predecessors, as the steepest incline against the load will be 1 in 100, compared with 1 in 60 at the Waterloo and City, and 1 in 30 at the City and South London. The weight of rail which it is intended to use will be 100lb. per yard. The style of cars will be like those on the New York Elevated Railroad. In these there is a wide passage at each end, with seats placed back to the windows, as in an omnibus. In the centre of the car the passage is narrower, and the seats are arranged in groups of four, as in an ordinary American railroad car. They will be mounted on bogie trucks, and will weigh nearly 13 tons each. The seating capacity of each car will be 48, and a train will consist of six or seven cars.

The City terminus of the line will be at Liverpool-street, just under the Great Eastern terminus. It will thus be possible to connect it by subways with the Great Eastern Station, of which the suburban traffic is estimated at 80,000,000, with Broad-street Station, which conveys 26,000,000 passengers annually, and with Bishopsgate Station of the Metropolitan. Passing under the latter, the line will run beneath Old Broad-street and Threadneedle-street, and along by the Stock Exchange, to the Bank Station. There is more traffic along Mansion House-street, as the short length of road between the Mansion House and the Union Bank is named, than in any other part of London, and it is beneath this that the new railway will pass. The whole of the roadway from Princes-street to Lombard-street, and from the Mansion House to the Royal Exchange flags, is to be excavated, and supported on columns, girders, and arches. The cavern thus formed will be egg-shaped, and will have a subway 15ft. wide running all round it. Two staircases terminating in passages will lead to this subway from the Exchange flags—the one close to Threadneedle-street, and the other bordering on Cornhill. There will be two other staircases, which unite in one long passage from the Poultry and Walbrook sides of the upper end of Queen Victoria-street. Besides these, there will be staircases leading to the subway at the Union Bank, corner of Princes-street, the north-east corner of the Mansion House, and the junction of Lombard-street with Cornhill. In consideration of the company obtaining permission to construct their station at this site, the public are to be allowed to use the staircases and subway, thus saving delay both to the pedestrians and to the vehicles, which have to be stopped to allow them to cross. The public subway will be about 20ft. below the street level, and below it will be another subway of the same width, in which water and gas pipes, telegraph, telephone, and electric light cables will be collected, so that it may never be necessary to break up the roadway in order to make any repair or addition to these. The station will be at a level about 10ft. below the subway which surrounds it, and with which it will be connected by broad staircases on the north and south. Besides a spiral staircase there will be four direct-acting lifts to take passengers down to the platform level, 65ft. below. The Bank Station, with its subways, staircases, and other accessories, will be the first part of the work which will be commenced, and it will be put in hand very shortly. Besides the Central London, it will serve for three other electric railways: it is to be the terminus of the Waterloo and City, the City and South London is to be extended to it from the Monument, and the line from Islington, which has received parliamentary sanction, will also be brought to this point.

After leaving the Bank Station, the Central London Railway will go under the Poultry and Cheapside, and then with a short curve into Newgate-street, where there will be a station behind the new building of the General Post Office. From Newgate-street it will pass under Holborn Viaduct to the next station, at the top of Chancery-lane. There will be a station at the commencement of New Oxford-street, called after the British Museum, and another at Tottenham Court-road, where the line will possibly connect with an electric railway which has been authorised from Charing Cross to Hampstead.

At Oxford-circus Station it is proposed to make connection with the "Baker-street-Waterloo" electric railway, and thence the line will continue under Oxford-street and Bayswater-road through Davies-street Station, just past New Bond-street, the Marble Arch Station, at the top of Edgware-road, Westbourne Station, close to the head of the Serpentine, and Queen's-road Station, at the top of the road of that name. At the next station, Notting Hill-gate, it will probably be connected by subway with the District Railway Station of the same name. There will also be a station at Holland-park, and then the terminus at Shepherds Bush is reached; this adjoins the Uxbridge-road Station of the Outer Circle, used by the Great Western, North-Western, and South-Western, and connecting with the Metropolitan and the District Railways.

The generating station is to be at the Shepherds Bush end of the line, and it will be possible to deliver coal direct from the trucks of the Great Western or North-Western Railways to the boilers. Triple-expansion condensing engines are to be used, the total horse-power being about 2,900. The dynamos will be direct current, low tension, at about 500 volts. The current will in the first instance be sent through the tunnels by a main conductor or copper cable, which is insulated, and placed clear of the line altogether. It is connected at intervals with the working conductor, which is a channel of steel, resting on blocks of glass, placed on the sleepers. The feed from the main conductor to the working conductor passes through the signal-boxes, so that the signalman can cut off the current from his section in case of emergency. The motor in front of each train picks up the current from the working conductor through shoes or brushes which slide over it. The current is carried back by means of the rails themselves, the ends of the rails being connected by copper strips to ensure electrical contact.

The engineers of the line are Mr. J. H. Greathead, Sir John Fowler, and Sir Benjamin Baker. The total cost will be about £3,000,000. The contract to construct the whole of the work and to provide the rolling-stock has been taken by the Electric Traction Company, Limited, of 16, Great George-street, Westminster; but it has not yet been settled into how many sub-contracts the work will be divided.

It is expected that the whole journey will take 25 minutes, of which the time from Oxford-circus to the Bank will be 10 minutes, including stoppages. The trains are to run at intervals of 2½ minutes, and when at full work there will be 25 trains in motion, each consisting of seven cars. This gives 336 people per train, and if the railway were to work for 16 hours per day during 333 days in the year (reckoning Sunday as one-third of a day), it would be able to take 85 million passengers over the whole distance. From this the company infer that, after allowing for one-way traffic, etc., they will easily be able to accommodate 100 million passengers per annum.

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 36.)

The commonest curve met with is a straight line. This statement may seem somewhat paradoxical at first sight, but a curve, mathematically, is any line in which the position of every point can be represented by an expression in terms of the co-ordinates used. The purpose of these articles

Digitized by Google

will be best served by adhering to what are known as Cartesian co-ordinates—that is to say, that method of expressing the shape of a line which we have already given. For the present, at least, we shall therefore describe the position of a point by reference to the two straight lines at right angles to one another, called O X and O Y above, and known respectively as the axis of X and the axis of Y.

We must first see that the position of a point in a plane is defined *exactly* by these means. We are given the two datum lines, O X and O Y, drawn on a sheet of paper, and by means of these are required to define the exact position of a point on that sheet. We must imagine the sheet of

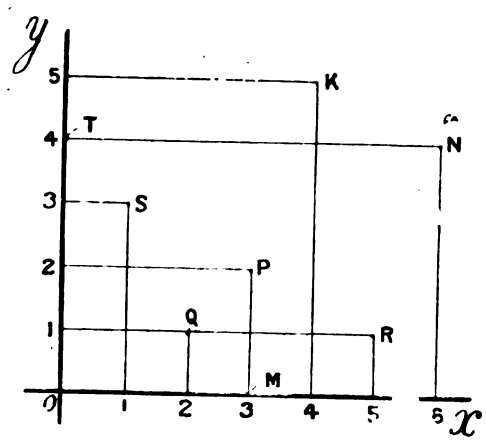

FIG. 5.

paper infinitely large, and the axes of X and Y each to extend to infinity in both directions, but their position in space fixed. The point where they cross, or "cut," one another is evidently a fixed point in space. We are thus in possession of a fixed point and two fixed directions in space. In Fig. 5, if we had to describe the position of point P, we should do so most accurately by saying that it was the point of cutting of two lines, one parallel to O Y, and cutting the axis of X at a distance of 3 from our fixed point, O, and the other parallel to O X, and cutting O Y at a distance of 2 from O; 3 is called the X ordinate and 2 the Y ordinate of P.

These two lines can only cut at this one point. Take an illustration: A man finds that from a certain spot in his field he can obtain a view of some particular object, and wishes to note the spot. His hedges run exactly at right

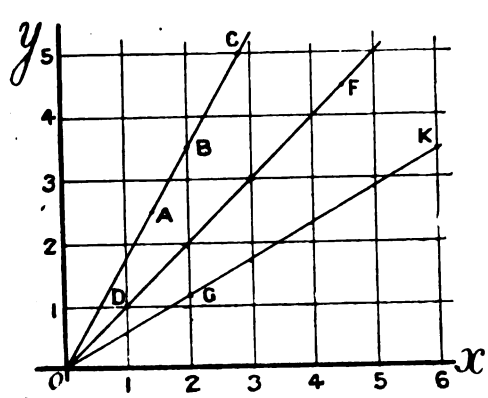

FIG. 6.

angles; he finds that by starting at a corner and walking 200ft. along one hedge, and then in a direction at right angles with it (*i.e.*, parallel to the other hedge) for 15 yards, he arrives at the spot. Any man to whom he tells this can find the spot by following those instructions. He has defined the spot exactly. A glance at Fig. 7 will show that points can be just as exactly defined if the hedges (or axes) are not at right angles. Also, it must be clear that he can arrive with just the same certainty at the spot by walking 15 yards along the other hedge first and then 200ft. parallel to the hedge by the side of which he originally walked. Or two men would find the spot by taking up positions at the hedges 15 yards and 200ft. respectively from a corner, taking care to keep the right distances for the right hedges, and walking out into the field each at right angles to his hedge; the spot where their paths crossed would be the spot with absolute certainty. If the contour of the field did not change, a man having these instructions could find the exact spot without any possibility of error hundreds of years after. This method then is exact.

If we wish to describe the position of the points, P, Q, R, S, T, M, N, K, in Fig. 5, we have only to give the distance of the point from O along each of the axes of reference O X and O Y. It is usual to do this as follows: P is the point (3, 2); Q is (2, 1); R is (5, 1); S is (1, 3); T is (0, 4); K is (4, 5); M is (3, 0); N is (6, 4). The invariable custom is to write the figure expressing distance along O X first and the distance along O Y next, and to separate the two by a comma. In Fig. 7 are given points which have the same notation, but with reference to two axes, O X^1 and O Y^1, which are not at right angles to one another, the points are obviously not the same as those in Fig. 5 if the point O is the same; but it is evident that the identically same points *could* be expressed by reference to either pair of axes. This latter method has little value and will not be again referred to. The question may arise, "How are we to represent a point which is below O X or to the left of O Y or both below O X and to the left of O Y?" To meet this contingency, all distances measured to the left of O along the direction of X O produced through O (we state it thus for clearness' sake; the axis of X is really infinitely long in directions both left and right of O) are called negative, as are also

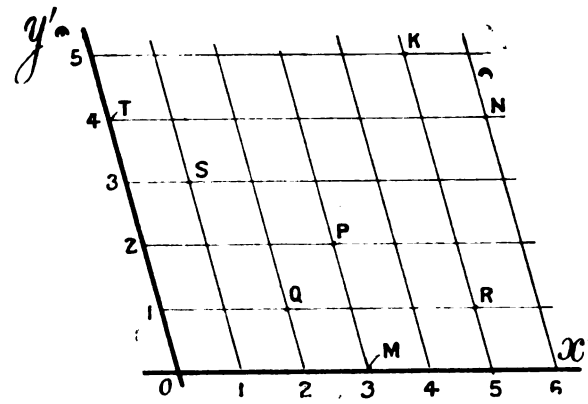

FIG. 7.

those distances measured below O in the axis of Y. We can therefore write something to mean any point we wish.

A line is an infinite number of points side by side; can we write down something which shall mean a line? Let us take a straight line first. In this work the scales along X and Y must always be equal, or we should be landed in endless confusion, but we have seen that in curves which represent facts the scales may be just whatever we choose to make them; just now we are not representing facts, but studying curves.

Can we write something which shall mean the line O D E F in Fig. 6? The point O is (0, 0); the point D (1, 1); the point E (3, 3); the point F (4·5, 4·5); of all these points the X ordinate is of the same value as the Y ordinate. Moreover, all such points would be on the line O D E F, as we see at once by filling in the points (2, 2); (4, 4); and (5, 5). Let us write $x = y$, meaning by "x" the X ordinate, and by "y" the Y ordinate. What can we take this to mean? It must mean more than a single point, for we need only write two *figures*, such as (1, 1) to mean a single point. But the letters x and y may be used as "variables" in this work, as in algebra, and with the most elementary knowledge of algebra we are aware that the expression $x = y$ is called an equation; that all letters and figures to the left of the sign = make up together what is known as "the left-hand side of the equation," and those on the right "the right-hand side"; also that when we have only x on one side and all other terms on the other side, we can without delay get a numerical value for x when the

Digitized by Google

numerical values of these terms are known to us. If we find among these terms a variable, say y, our equation informs us that we may substitute for y any number we like; the equation gives us what the value of x will be when y has the value we assign to it. Therefore, our equation above tells us simply that, no matter what value we give to y, x has the same value. Obviously, then, if x means the X ordinate of a point and y its Y ordinate, this equation describes as many points as we can think of values to give to y. This number is infinite. The equation $x = y$ describes, therefore, an infinite number of points whose X ordinates and Y ordinates have the same value. If we find a lot of such points on the paper and join them, we get the straight line O D E F. This is not a mathematically rigid proof, of course—we do not desire one—but it suffices for the scope of these articles to show how at least this one line may be expressed by an equation. Briefly, $x = y$ now has a definite meaning for us. It is, of course, evident that O F is only a part of the line $x = y$; $x = y$ is a line whose extent is only limited by our power to give values to x or y.

(To be continued.)

NOTES ON THE RECONSTRUCTION OF A SMALL CENTRAL-STATION PLANT.*

BY FRANKLIN L. POPE.

The financial condition of the smaller central-station electric lighting plants throughout the country is at the present time by no means satisfactory, and in too many instances cannot even be truthfully said to be encouraging. A survey of the field shows that very few such plants located in towns having less than 10,000 inhabitants are earning more money than is necessary to meet their operating expenses and to provide for indispensable current repairs. In the State of Massachusetts, in which the operations of all electric lighting companies are by law made a matter of public record, it appears from the latest reports that the aggregate liabilities of the 57 companies operating in that State, including stocks, bonds, and floating indebtedness, amounted on June 30, 1894, in round numbers, to 14,000,000dol., nearly all of which stands charged to construction account. The net earnings for the preceding year were 1,000,000dol., or about 7·1 per cent. on the total investment—a sum obviously quite insufficient to provide for depreciation and at the same time pay a fair dividend on the capital which has gone into the business. But if half-a-dozen of the larger plants, in cities like Boston, Lowell, Worcester, Springfield, Lynn, and Fall River, were excluded from the list, the showing for the smaller plants would be even far worse than it now appears.

Many of these small plants were started at an earlier day than could have been justified by any reasonable estimate of the business then in sight, and now find themselves hampered by inconvenient buildings and with unsuitable machinery bought at high prices and encumbered with defective business methods, which experience has shown to be wholly inconsistent with the dictates of good judgment.

With the owners of many of these plants, it has become a very serious question whether the easiest way out of the dilemma which confronts them may not be to relegate the entire plant to the junk shop and the scrap-pile, and commence over again with new buildings, modern machinery, and improved methods of administration. When the necessary capital is readily forthcoming, there can be no doubt that this would often be the wisest course of procedure, but for obvious reasons it is one which is not always nor even usually practicable. The alternative is to remodel the existing plant, bringing it as nearly as may be into accordance with the best modern practice, and utilising so far as possible the old material, a course which at least has the merit of avoiding an undue expansion of the construction account—in most cases already sufficiently burdensome.

Having been called upon during the past year to advise the owners of a plant of the character above referred to in reference to certain changes which had been suggested as desirable, and having afterwards been employed in a professional capacity to design the work and superintend its execution, I have thought that some account of what we undertook to do, and how we did it, might not be without interest to the members of the institute.

The Great Barrington, Mass., Electric Light Company was organised and commenced business in 1888. The population of the district intended to be served was about 3,000, and most of the expected consumers were located within 2,000ft. of the point decided upon for the station. This was built of wood in the most inexpensive manner possible, and was placed alongside the railroad for convenience in receiving coal, although at the same time the danger from fire was materially increased. The original outfit was an Edison three-wire, equipped with a pair of 250-light 110-volt dynamos, and the company commenced business with 281 lights on contract at 10dol. per year each, wiring free. The centre of distribution was 1,800ft. from the station, necessitating over a ton of copper in the feeders alone. Generally speaking, the plant was well laid out and well built as things went in those days. The two dynamos were belted to a single 80-h.p. Armington and Sims engine. The original cost of the plant was about 16,000dol. The following year a Schuyler arc plant for street-lighting was added, carrying 35 arcs, nominally of 1,500 c.p., which was run from the same engine and boiler. In 1890 the plant was considerably enlarged by the addition of a second arc machine, a Westinghouse 500-light alternator, and a second engine and boiler of the same capacity as the first. An 80-kilowatt Westinghouse dynamo of more modern type was afterwards substituted for the original one.

Upon examining the plant last year, I found the Edison machines carrying on Saturday evenings a maximum load of some 450 lights, while three evenings in the week (with the stores closed) it fell to perhaps half that amount. The two Schuyler machines, with an aggregate capacity of 55 to 60 lights, were carrying about 38 to 40, or an equivalent of that amount, while the Westinghouse machine was seldom as much as half loaded, carrying a maximum of possibly 500 lights during three or four months of the summer season, and not much more than one-fourth that amount the remainder of the year. Necessarily, with so many dynamos of different types and with such a variable, yet small, average output, the consumption of coal was excessive as compared with the light delivered and paid for.

The street lines, according to the usual practice, were of No. 6 Brown and Sharpe weather-proof wire, the poles were of cedar of good size and fitted with pine or spruce cross-arms, with common green glass insulators set upon wooden pins. In consequence of a silly prejudice which had been fomented amongst the citizens by interested parties against permitting poles to be set in the streets, the wires, in a very great number of instances, had been attached, by cross-arms or brackets, to the trunks of the immense elm trees with which the streets of the town were shaded—a practice which occasioned an enormous loss of current every wet night, as well as much irregularity in the performance of the lights. The effect on the trees was by no means salutary, while the appearance was as much worse than that of poles in the streets as could possibly be imagined.

The village of Great Barrington extends for the most part along a single broad thoroughfare for a distance of nearly three miles, and the street-lighting circuits are consequently very straggling. The 1,500-c.p. lamps, which were suspended at intervals of 800ft. to 1,000ft., were actually of very little service in illuminating the densely-shaded streets.

After a careful consideration of the situation, keeping in view the greatest possible reduction of present and future operating expenses, it was determined that the wisest course to pursue would be to consolidate the whole service so that it could be supplied by one dynamo, in place of five underloaded ones. In pursuance of this plan it was decided to adopt the two-phase alternating system, at a maximum pressure of 2,100 volts in the primaries, and 105 volts in the secondaries, with a frequency sufficiently low to permit the advantageous use of induction motors if

* Paper read before the American Institute of Electrical Engineers, Niagara Falls, June 27, 1895.

Digitized by Google

required. It was furthermore decided to abandon the steam plant, and to make arrangements to utilise some one of the excellent water powers which were available within practicable distances. Under ordinary circumstances, I should have hesitated to recommend the substitution of water power for steam as the sole source of power for the operation of an electric lighting plant. Water power is an invaluable auxiliary, and when conveniently available for use in conjunction with steam, may often be made to save a very large coal bill in the course of a year. On the other hand, the excessive fluctuations to which it is subject—which are scarcely realised by those but casually acquainted with the subject—render it in most cases a very uncertain reliance for a business which is compelled to go on, perforce, every night in the year, and which cannot suspend operations, as an ordinary manufactory does, if worst comes to worst, for a week or two at a time. Even a water privilege which, during 10 months of the year, furnishes twice as much power as is needed, and even more, may be expected to fall off during one of the extraordinary dry seasons which occur at intervals of from five to ten years to one-third its usual amount. In such a case, an electric plant solely dependent upon water power would find itself in a most undesirable predicament.

In the present instance, the choice of a water privilege finally reduced itself to two sites, one in the town itself, within half a mile of the centre of consumption, and the other at Glendale village, seven miles distant, both situated on the Housatonic River. The privilege first mentioned being already occupied by a woollen factory, only the surplus water was available, but this was known to be quite sufficient for the requirements of the electric company at least nine months in each year, leaving three months to be run by steam. It had the advantage of being close at hand, and was capable of being fitted up at a moderate cost. As to the Glendale privilege, it was necessary to be very sure that the lowest water of a dry summer would give all the power required to run the plant without the aid of steam. Having invariably found the value of a water power to be greatly exaggerated, not only in popular estimation, but in the opinion of its owners, the matter was investigated with much care. From the official State map of Massachusetts, it was ascertained that the area of the drainage basin of the Housatonic above the Glendale dam was 269 square miles. J. T. Fanning, a leading authority, from an extended examination of the recorded observations on the rainfall and flow of the New England rivers, reaches the conclusion that a watershed of the area mentioned may be estimated to yield the quantities of water given below:

CUBIC FEET OF WATER PER SECOND PER SQUARE MILE.

Minimum (15 days of least summer flow)	0·25
Mean (120 days, usually July to October, inclusive)	0·90
Maximum (flood volume)	93·00

It will be noticed that the flow in extreme dry weather is less than one-third of that which may be depended upon through the remainder of the year.

The distribution of rainfall throughout the year should be studied. It is often materially modified by local geographical conditions. The diagram shows that the distribution on the headwaters of the Housatonic is quite different from the normal type of the north-eastern region. The same may be true of other rivers.

While this investigation was going on, it was discovered that actual measurements of the volume of water in the Housatonic River had been made in 1878 by the engineers of the New York Department of Public Works, with reference to its utilisation as a future source of water supply for that city. The minimum summer flow was found to be (as given in the engineer's report) 0·34 cubic foot per second per square mile. It was also learned that measurements made on several different occasions at Birmingham, Conn., in very low stages of water, gave an average of 0·32 cubic foot per second per square mile. It was, therefore, assumed that Mr. Fanning's estimates were at least on the safe side. The greater volume of water found by the actual measurements is doubtless due to the fact that there are some five or six square miles of reservoirs, consisting of natural and artificial lakes, on the upper waters of the Housatonic, which are drawn upon by the numerous mills on the river as an extra supply during the season of drought.

A minimum flow of 0·25 cubic foot per second per square mile would give at Glendale 4,035 cubic feet per minute. Multiplying this by the weight of a cubic foot of water (63·3lb.) gives 255,415 foot-pounds, which, divided by 33,000, gives 7·74 gross horse-power per foot of fall, or a total of 99·6 h.p. for the 13ft. fall at Glendale. The average efficiency of a good turbine may safely be taken at 75 per cent., which would give 67·9 as the available horse-power during the whole 24 hours, in time of lowest water. In electric lighting, however, the great bulk of work is done within a period of about four hours (in summer time), and hence it is possible, in case there is sufficient area of pondage above the dam, to increase this capacity by storage at least fourfold, which would raise the limit of minimum available power during lighting hours to 271·6 h.p., an amount which was considered to be ample to meet all the probable requirements of the Great Barrington plant for many years to come.

While negotiations were still pending with the owners of the Glendale privilege, and also the one in the village already referred to, overtures were received from a manufacturing company owning a third exceptionally desirable privilege on the same stream at an intermediate point considerably nearer than Glendale. This company had only recently completed a new dam, head-gates, raceways, etc., at a very considerable expense, and was willing to lease the complete establishment, including a new McCormick turbine of 325 h.p. and a two-phase Stanley generator of corresponding capacity, at a monthly rental based upon the actual output as measured in kilowatt-hours at the dynamo terminals, provided that a certain minimum monthly consumption was guaranteed. With the same volume of water as at Glendale, the fall at this point was 20ft., assuring at least 417 h.p. at lowest water during lighting hours. All the hydraulic apparatus and appointments were of the best possible construction, and well calculated to ensure absolute permanency of operation.

The minimum rental required was somewhat less than the amount of the coal bill of the Great Barrington company for the preceding fiscal year, but while the immediate saving in operating expenses was not large, the acceptance of the proposition would place the company in a position to reduce its rates to consumers, for the reason that its output might be very largely increased without materially augmenting its operating expenses. A lease for a term of years was accordingly closed.

In laying out the plant it was determined to bring the main feeders directly to a distributing station in the village to be used principally as a convenient headquarters for testing the circuits and controlling the street-lighting service. In laying out the transmission line a surveyor was employed, and a preliminary line was run directly from the power-house to the distributing station. The air-line distance was found to be 5·15 miles. With the assistance of the surveyor the actual line was then staked out, going directly across country and keeping as near as circumstances permitted to the transit line. About half the distance the transit line was found to so nearly coincide with existing highways that the consent of the local authorities was obtained to set the poles along the highway location; the remainder of the route lay principally through uncultivated land of little value, so that a comparatively small expenditure was sufficient to secure a release from all claims for land damages. This enabled the line to be located with long stretches absolutely straight, avoiding all sharp angles, a very important consideration when heavy wires are used. The poles were of selected chestnut with natural butts, usually set 5ft. in the ground at maximum intervals of 125ft. The poles were ordinarily 25ft. long and 8in. thick at the small end. Shorter poles were sometimes used on elevations and longer ones in depressions, in order to equalise the strain as much as possible. The insulators used were of the large double-bell white porcelain type (German Government standard), and were imported by us from Berlin. The insulator of the top wire is set upon a malleable iron stem 14in. long screwed into the top of the

Digitized by Google

pole, which is tapered to 5in. diameter and protected from splitting by driving on a wrought-iron ring. The tapered part of the pole, as well as the top, was given a coating of mineral paint mixed as thick as it could be spread with a brush. The insulator of the second wire is carried on a malleable iron goose neck, screwed into a $\frac{5}{8}$in. hole bored in the side of the pole, in such position as to bring the wires about 16in. apart. Another hole was bored on the opposite side of the pole, intended to take the goose neck of the third wire at some future time, leaving the same interval between the second and third wires. The porcelain insulators are fixed to their iron supports by a packing of oakum placed between the screw threads, which serves to prevent any danger of breakage by expansion or contraction. The line wire is laid in a groove formed in the top of the insulator, except upon the curves and angles, in which case it is tied at the side in a circumferential groove, as is usual in this country. The German method of tying is quite complex and unnecessarily strong; in case of undue strain, if anything gives way it had best be the tie wire. We therefore devised a simple tie which was easily and quickly applied, and which has so far served an admirable purpose. We were obliged to string the wires during very cold weather; sometimes as cold as 8deg or 10deg. below zero, and hence it was necessary to strain them very tight. A block and fall and a well-trained horse were used in pulling up, usually six or seven spans of one wire at a time. The hook of the block was always attached to the copper wire, whether bare or insulated, with a chain knot made of $\frac{3}{4}$in. rope. The feeder wires were of No. 3 Brown and Sharpe soft copper, covered with weather-proof "insulation" along the highway (as a concession to enlightened public opinion), but elsewhere bare. The lengths of wire were joined with McIntyre twisted couplings; the unusual strain we had to put upon them occasionally pulled one apart, and this led us, out of abundant caution, to solder them, although this was done for mechanical rather than for electrical reasons. Only two feeder wires have as yet been strung, providing for a single-phase current from one side of the two-phase generator, but it is the intention to run a third feeder hereafter, which will enable two-phase induction motors to be connected to the same distributing system.

A pair of telephone wires of No. 12 steel were strung below the feeder wires, and these were supported upon small German porcelain insulators on iron goose necks on opposite sides of the poles. These wires were transposed at intervals of about a mile, in order to eliminate the inductive effects of the alternating current in the feeders. The feeder lines were carried under the railroad at an undergrade crossing by placing the insulators upon iron brackets leaded into the stone abutments. The plan of construction above described makes a strong, handsome, and durable line, while the insulation of the circuit, even in the worst of weather, is simply faultless.*

The system has been planned to deliver the current at the distributing station at a uniform pressure of 2,100 volts. Two distributing centres were fixed upon in the old Edison three-wire network, and at each of these points a pair of large transformers, having a ratio of 20 to 1, were fixed upon a pole, with their respective primaries in series between a pair of branch feeders from the distributing system, and their secondaries were coupled in series in like manner with the neutral wire between them. None of the consumers on the old Edison system knew when the change had been made to the new service from anything they were able to notice in the behaviour of the lights.

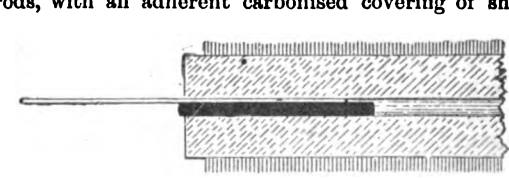
The next thing done was to reconstruct the street-lighting system. In place of the 36 arcs of 1,500 nominal candle-power formerly in use, we substituted 126 incandescent lamps of 50 volts and 32 c.p., placed in Iona fixtures projecting horizontally from the poles 14ft. above the ground. The lights, as a rule, were fixed uqon every alternate pole, but in the business centre, the street being broad, they were placed on each side at intervals of about 250ft., and staggered, so as not to come opposite each other. A Shallenberger shunt cut-out was applied to each lamp. The usual number of lamps in each circuit was 42, although we have since placed, in some cases, as many as 47 in one series without reducing the brilliancy of illumination sufficiently to be noticeable by anyone but an expert. One end of each street-lighting circuit is joined to a special feeder leading to the sub-station, where it is connected with the main feeder through a knife-switch. The other end of each lamp circuit is connected to any conveniently located branch feeder of the regular commercial lighting service. Each lamp circuit has, or will have, a fuse-block and cut-out enclosed in a weather-proof box at each end, where it joins the opposite feeders. These 32-c.p. lamps, when run at full candle-power, furnish a most satisfactory illumination and give the streets a very attractive appearance. So far as possible each lamp was located with the aid of a transit and level, so as to get them in absolutely straight lines both vertically and horizontally, a precaution which adds materially to the decorative effect. It is admitted by all that the streets of the town are much more satisfactorily lighted by the incandescents than they formerly were by the arc lamps, while the actual cost to the company is considerably less. The new lamps were cut in, one at a time, on the old arc wires, jumpers being temporarily placed across the terminals until everything was in readiness to discontinue the use of arc machines.

One of the most marked advantages of the series street-lighting system, especially when shunt cut-outs are used, is its great flexibility and convenience. For example, instead of placing from 40 to 45 50-volt lamps in one series, we may use 20 to 30 100-volt lamps, or if an odd number be required, less than is necessary to make up a circuit, the deficit may be supplied by adding extra shunt boxes in series at any convenient point in the circuit, until the pressure has been reduced to the required point. From time to time, as new lights are added, these spare shunt boxes are one after another brought into use in connection with them. Sometimes, also, we temporarily instal extra street lights by connecting them in parallel to the secondary mains of the regular commercial service, ultimately transferring them to new series circuits.

(To be continued.)

VELVO-CARBON.

The Battery and Motor Company, Limited, Bower-road, Victoria, N.E., send us a new list giving particulars of their velvo-carbon battery. We illustrate herewith a full-size section of the connection end of a 13mm. velvo-carbon rod for natural or chemical (gasing) depolarisation. These are hollow carbon core rods, with an adherent carbonised covering of short pile



cotton velvet. They are suitable for use as the negative electrode of a battery, employing either a simple sulphuric or a nitric solution. They are provided with a pure silver-wire connection. This connecting wire is held in position (and in perfect contact with the wax-protected end of the hollow carbon) by a rivet plug, which expands after being driven home.

* I regret that I am unable to present any actual measurements of the insulation of the line of the Great Barrington Company, no opportunity having occurred, since the work was completed, of making tests under atmospheric conditions of minimum insulation. Several years ago, however, while engaged in telegraphic service, I made a series of nearly 100 separate tests in rainy and foggy weather, extending over a period of five years, of a set of 10 porcelain insulators of the same make and pattern in every particular as those now on the Great Barrington line, erected on a house-top in the city, and therefore much exposed to smoke and dirt. These measurements gave a mean resistance of 28 3 megohms, and a minimum resistance of 19 megohms per insulator. On a metallic circuit, therefore, the minimum insulation resistance at each pole would be 38 megohms. On the Great Barrington line of 28,260ft., there are 250 poles and other supports, and hence we may assume that the minimum resistance of the insulation of the circuit as a whole would be 152,000 ohms. The current loss by leakage is found by dividing the mean voltage by the insulation resistance: $\frac{2,200}{152,000} = 0{\cdot}014$ ampere; an amount too small for serious consideration.

NEW METHOD OF MEASURING ELECTRIC CAPACITIES, BASED ON THE SENSITIVENESS OF THE SKIN.*

BY H. BORDIER.

The principle of the method which I am about to describe is based upon an experiment by Prof. d'Arsonval.† If condensers of increasing capacity are placed successively in series on the same induction coil, and if we seek, either by the aid of a rheostat or by moving the coil by predetermined steps, the moment in which the least sensation produced by the current on the skin is perceived, it is found that this moment varies for each added capacity.

If we have, for example, a microfarad divided into tenths, it is easy to find two positions either of the rheostat or of the coil which correspond to the initial sensations produced by each tenth of microfarad added. In taking the capacities as abscissæ, and the different positions of the rheostat or of the coil as ordinates, a curve is obtained which represents the variation of the cutaneous sensitiveness with the different added capacities. This curve being established, it is sufficient to seek the moment of the appearance of the sensation produced by the faradic current, the coil being furnished with the condenser the capacity of which it is desired to know, and which can then immediately be read from the curve.

As is seen, this method utilises the minimum sensitive effect produced on the nerval terminations of the skin. If it is very difficult to appreciate the equality of two successive sensations, it is, on the other hand, very easy to distinguish the instant in which a sensation commences.

In order that the impressed surface and that the conditions of imbibition of the epidermis may remain the same during an experiment, it would be well to immerse the fingers in two basins containing water and connected to the two terminals of the induction coil.

Here is an example of the results obtained by this method. The coil used had a resistance of 668 ohms, the diameter of the wire was $\frac{1}{8}$mm., and its length 1,300 metres. The induction apparatus should be furnished with a Fizeau condenser, so that tolerably regular interruptions may be effected. Two wires go from the two terminals of the induction coil to two small crystallisers full of water, and at the bottom of which is a metallic plate. Immerse the index and middle fingers of each hand in the basins. We must first ascertain the position which the coil should occupy in order that the minimum sensation may appear—19·25 is found. A microfarad divided into tenths is then put in series, and the minimum sensation is experienced for the following positions of the coil:

Added capacities. Microfarad.	Position of the coil. Centimetres.
0·0	19·25
0·1	16·75
0·2	15 5
0·3	14·5
0·4	13 75
0·5	13
0·6	12 5
0·7	12
0·8	11·6
0·9	11·25
1	11

It may be remarked that in proportion as the capacity of the coil augments it is necessary to bring it gradually nearer and nearer. If the curve be constructed as mentioned above, it is found that all the points determined experimentally are placed pretty regularly on the same line. This result proves that the method is capable of supplying a tolerably close approximation.

The following are, in fact, the capacities found for two condensers: condenser *a*, 0·915 microfarad; condenser *b*, 0·91 microfarad. The ballistic galvanometer method furnished these figures: condenser *a*, 0·912 microfarad; condenser *b*, 0·915 microfarad.

The sensitive effects are not always diminished when the capacity of a coil is augmented. If the latter is a thick wire coil of low resistance, it will be found that the sensation becomes more powerful in proportion as the added capacities go on increasing. With a coil of 0·72 ohm resistance, the wire being 60 metres long and $\frac{13}{10}$mm. in diameter, I have obtained the annexed figures:

Added capacities. Microfarad.	Position of the coil. Centimetres.
0·0	9·5
0·1	10
0·2	10·4
0·3	10·8
0 4	11·25
0·5	11·7
0·6	12
0·7	12·5
0 8	12·9
0 9	13·4
1	13·8

It is here seen that it has been necessary to place the coil further away instead of bringing it nearer, as in the preceding case, in proportion as the capacity increased. However it may be, the method of measuring the capacities remains applicable in every instance.

There is a capacity which it is very interesting to know, and regarding which we have not very precise data—I mean the capacity of the body of man. The method which I have just indicated allows a very approximate measurement of this capacity to be obtained. The insulated object is placed in tension on one of the wires which connect the coil to the standardised condenser; a key or plug allows of the body being taken off the circuit or put in it. Results:

Added capacities at the coil. Microfarad.	Variations of the coil. 1st experiment. Centimetres.	2nd experiment. Centimetres.
0 0	20 00	19 25
0·1	17 75	16 75
0·1 + the body	17 7	16 7
0·02	16 75	15 5

In doing each curve on squared paper of large size, we find for the value of the capacity of the body: first experiment, 0·002 microfarad; second experiment, 0·003 microfarad; average value, 0·0025 microfarad. This capacity is about 58 times greater than that of a homogeneous conductor, the surface of which would be equal to that of the human body. We may be permitted to think that this capacity, relatively large, of the human body is due to phenomena of condensation occurring in the heart of the organism.

LEGAL INTELLIGENCE.

CLAIM FOR ELECTRIC LIGHTING WORK.

In the Bloomsbury County Court on Friday, his Honour Judge Bacon had before him the case of Dawson *v.* Foster, in which the plaintiffs, Messrs. Dawson, Limited, electrical engineers, sought to recover payment of an account in respect of the installation of electric light throughout the defendant's house at Portman-square. It appeared from the evidence called on behalf of the plaintiffs, that the order for the work was given by the defendant's wife, but the husband had always been looked upon as the responsible party. When the work was completed, application was made to him for payment, but he denied liability on the ground that he never authorised his wife to give the order.

For the defence, **Mr. Foster** was called, and said he allowed his wife ample means to pay for general domestic expenses, and had absolutely forbidden her to pledge his credit in any way whatever. He was never even consulted in this matter, and therefore he did not consider he was liable.

His **Honour**, in giving judgment, said that cases of this kind were a great hardship on tradesmen, but they ought to be more careful to get the authority of husbands before carrying out orders which were given by the wife. He (the judge) had little doubt but that the defendant must have known that this work was being carried out, and no doubt he was enjoying the benefit of it, but in view of the evidence which had been given, he was afraid the plaintiffs could not recover, and therefore judgment must be for the defendant, but he should certainly not allow any costs.

WOOD v. WOODHOUSE AND RAWSON.

A summons for leave to institute proceedings in the action Wood *v.* Woodhouse and Rawson, Limited, appeared in Mr. Justice Vaughan Williams's list on Wednesday. At the rising of the Court, the case not having been reached, **Counsel** asked if his lordship would fix an early day for hearing the application. It

Digitized by Google

was a case for consideration as to whether proceedings should be taken against the directors or not, and his lordship had directed a meeting of the shareholders to consider it. They had met, and it was desirable that the matter should be disposed of as soon as possible.

His **Lordship** directed application to be made to his clerk as to whether there was a vacant day, and if there was it would be given to this case.

ACTION AGAINST THE PRESCOT DISTRICT COUNCIL.

In the Queen's Bench Division, Mr. Justice Grantham and Mr. Justice Wright, sitting as a divisional committee, have heard the case of the British Insulated Electric Lighting Company against the Prescot Urban District Council, which was an application by counsel to mark the case urgent, and that it might be put into the list for next Monday. The Court granted the application.

BARCLAY v. NEW ZEALAND ELECTRICAL SYNDICATE.

On Saturday Mr. Justice North had before him a motion for judgment in a debenture-holders' action which came on by consent. So far as was known, there had only been one issue of debentures, which was for £30,000, and the plaintiffs held the whole of the issue. The company was formed to light the city of Wellington, in New Zealand, with electricity. The action was commenced last March, on the ground of jeopardy.

Mr. Justice North made an order that the plaintiffs were entitled to a charge, continued the receiver and manager, and directed the usual accounts and enquiries.

NEW BRITISH ELECTRICAL INSTALLATION.

Mr. Baker, in the action of Martin *v.* the New British Electrical Installation Contractors, Limited, on Thursday last week, asked Mr. Justice Kekewich to appoint a receiver and manager, describing the case as urgent.

Mr. Fawcus, appearing for the company, said they could not resist the application, and his **Lordship** appointed Mr. Lester, of Worcester, to the double position, but expressly refused to give any directions as the management.

COMPANIES' MEETINGS AND REPORTS.

WEST AFRICAN TELEGRAPH COMPANY, LIMITED.

The annual general meeting of the above Company was held yesterday at Winchester House, E.C., Sir Henry Mance, C.I.E., M.I.C.E., occupying the chair.

The **Chairman**, in moving the adoption of the report, stated that at previous meetings the results to ordinary shareholders had not been satisfactory, but there was now a better prospect. The death of Mr. Thomas Fuller, one of the directors, had occurred during the year, and he would be much missed. The chairman ran over the items of the account (an abstract of which was given in our last issue), and stated that there was a reserve of £21,000, and the directors had arrived at the conclusion that they should carry the whole balance of the net revenue to the reserve fund. This was the soundest policy to adopt. The revenue and the small amount of expenses in connection with repairs justified the payment of a small dividend. The Company was getting into a sound financial position, and the debentures were at a better price in the market. The reduction of the tariff to the Cape had given satisfaction to traders, and had proved of no disadvantage to the Company. Their cables were in good working order, the efficiency of the system had been improved, and the health of the staff was good. There was an increased revenue with a decrease in working expenses and in the loss by exchange.

Mr. J. D. Pender seconded the motion, which was carried unanimously.

The **Chairman** moved, and **Mr. J. D. Pender** seconded, the re-election of Mr. Robert Kaye Gray and the Hon. A. G. Brodrick as directors. The motion was adopted.

The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., were re-elected.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors: James Staats Forbes, Esq., chairman; the Earl of Lichfield, Major Samuel Flood Page, Joseph Wilson Swan, Esq., F.R.S., Ernest Villiers, Esq.

Report of the directors to be presented at the ordinary general meeting of the Company to be held at the Cannon-street Hotel, E.C., on Monday, July 29, at 2 p.m.:

The profit and loss account shows a credit balance of £25,876. 3s. 2d. After providing for the interest accrued upon the £100,000 debenture stock, there remains a balance of £21,376. 3s. 2d. available for distribution. An interim dividend at the rate of 5 per cent. per annum having already been paid in respect of the first half-year ending December, 1894, a further payment at the rate of 5 per cent. per annum in respect of the second half is recommended, the balance of £3,702. 5s. 2d. being carried forward. The business of the Company during the year has been satisfactorily maintained, notwithstanding the severe competition which has set in since the expiration of the Company's patents. The liquidation of the Swan United Electric Light Company, Limited, is now practically completed, and the final meeting for winding up will shortly be held. The directors have to report the resignation of his seat at the Board by Shelford Bidwell, Esq., F.R.S., and the election in his place of Joseph Wilson Swan, Esq., F.R.S. The Earl of Lichfield and Ernest Villiers, Esq., retire by rotation from the Board, and offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, offer themselves for re-election.

PROFIT AND LOSS ACCOUNT, YEAR ENDED JUNE 30, 1895.

EASTERN TELEGRAPH COMPANY, LIMITED.

The forty-sixth half-yearly ordinary general meeting of this Company was held yesterday at Winchester House, E C., the vice-chairman, the Marquis of Tweeddale, presiding in the absence of Sir John Pender.

The **Chairman**, in moving the adoption of the report and accounts for the half-year ended March 31, 1895, a summary of which appeared in our last issue, said that the revenue for the period amounted to £420,526, from which was deducted £98,060. 4s. 8d. for the ordinary expenses and £52,730. 0s. 2d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £3,222. 19s. for depreciation of spare cable, £1,813. 5s. due to revaluation of currency assets, and £5,812. 4s. 7d. for income tax, there remained a balance of £258,887. 6s. 7d., to which was added £59,175. 16s. 6d. brought from the preceding half-year, making a total available balance of £318,063. 3s. 1d. From this balance there had been paid interest on debentures and debenture stock, £27,514. 12s. 8d.; dividend on preference shares, £20,296. 6s. 8d.; an interim dividend of 2s. 6d. per share on the ordinary shares,

Digitized by Google

£50,000; total, £97,810. 19s. 4d., leaving a balance of £220,252. 3s. 9d., out of which the directors placed £9,000 to the reserve fund for maintenance ships and £100,000 to the general reserve fund. An examination of the message receipts showed that there was a small decrease in the traffic with India, a considerable increase in that with countries beyond India (Australia, etc), and a good increase in that with South Africa, doubtless owing to the activity in mining operations which has prevailed there for so long. He announced that the negotiations which had been conducted with the home authorities and the various South African Governments with respect to the continuation of the subsidies now payable for telegraphic communication with South Africa had been brought to a satisfactory termination. He had just received a telegram from Sir John Pender, in which he said: "Arrangements just completed with the Cape, Natal, and Transvaal ensure us 15 years' prosperous traffic"; the consideration being the lowering of the tariff. They had laid about 300 miles of new cable on the Bombay and Aden section. The property altogether was in a very prosperous condition, and the management was both efficient and economical. He moved that a final dividend for the year ended March 31, 1895, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares, be paid.

Mr. Nicholl seconded the motion.

The **Chairman** said, in reply to **Captain Goodsall**, that the 300 miles of new cable on the Bombay and Aden section were laid in different portions, but the last repairs were at the Bombay end; and, in reply to **Mr. Baines**, that they would be glad as soon as the reserve fund was sufficiently large to increase the dividends payable.

The motion was then unanimously carried, and a vote of thanks to the chairman concluded the proceedings.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

First annual report of Mr. Charles Fitch Kemp, the voluntary liquidator of the above-named Company, to be submitted to the shareholders at an extraordinary general meeting to be held at 73, Lombard-street, E.C., on Monday, July 29, at 2 30 p.m.:

In submitting my first report and statement of accounts I have to remind the creditors and contributories that the basis upon which I accepted the liquidation of this Company was, shortly, as follows: That each asset—viz., the stock-in-trade and plant, and a debt owing to the Company in New Zealand from the New Zealand Electrical Syndicate—would be sufficient to pay off the first debentures; that the uncalled capital of the Company would be sufficient to pay off the second debentures, and would probably provide a surplus of cash which would pay a substantial dividend to third debenture-holders; and that ultimately the unsecured creditors would be fully paid, and some return would be made on the share capital, when time had been given to realise the holding of the Company in the shares of the New Zealand Electrical Syndicate. This forecast of liquidation appeared at the time to be based on reliable grounds, but it has entirely failed of realisation, owing to two main causes, and the position now is that I have borrowed the sum of £3,000 on a transfer of the first debentures (which have otherwise been paid off), and that there remains due on that loan about £2,500, and that the only assets immediately available to meet that loan are the shares in Easton, Anderson, and Goolden, Limited, hereinafter more particularly referred to. The uncalled capital will not be sufficient to pay off the second debentures of the Company, and the realisation of the cash assets in New Zealand is indefinitely postponed. I have already said that there are two main causes which have led to this unfortunate result. The first and leading cause is the breakdown of the firm of Miles and Co., Limited. A director of that company was also a director of this Company, and he approved and endorsed the scheme for settlement of the affairs of this Company which was submitted to me, as before mentioned, but the keystone of the scheme was the payment by the contributories of the amount due from them, and Miles and Co., Limited, were responsible to this Company for no less a sum than £3,500, none of which I have yet been able to collect. Consequently, the claim of the second debentures, instead of being fully paid off and leaving a tangible surplus, remains unsatisfied, and unless, therefore, a very substantial dividend is recovered from Miles and Co., Limited, as to which I am unable to speak, I can see no immediate prospect of discharging them. The other cause is this: The plant of the Company in New Zealand was taken over by the New Zealand Electrical Syndicate as a going concern, and upon terms of repayment out of realisation which it was calculated would rapidly place this Company in the possession of funds. The debt was calculated to amount altogether to between £3,000 and £4,000, which would have been remitted from time to time as moneys were collected; but the New Zealand Electrical Syndicate had executed debentures on which default had not arisen, and which debentures were held by the Gas and Water Trust. The Gas and Water Trust, as holders of these debentures, procured from the New Zealand Electrical Syndicate, by vote of a majority of the Board, which had then control, a resolution in favour of the appointment of a receiver. Now, without encumbering this report with the details of disputes which arose between the shareholders of the Electrical Syndicate and the Gas and Water Trust, I was compelled to take steps to protect the interests of this Company in the assets of the syndicate, as I was advised that the syndicate's existence depends wholly upon the concessions and contracts it has secured in New Zealand and its Act of Parliament there, and that the appointment of a receiver might have a most disastrous effect upon all interests in the Company, whether of debenture or share capital. I thought that the gravity of the step taken by the Gas and Water Trust had not been adequately considered, and I instructed the solicitors acting for me in this liquidation to recall the shares to which I am entitled as liquidator, and which had been outstanding in the name of Mr. Roderick Pryor, and had been used by him for the purpose of qualifying as directors the nominees of the Gas and Water Trust. In this way I have reacquired some share in the control of the syndicate, but I have every desire and intention of co-operating with the Gas and Water Trust in the management, so as to duly preserve the interest of the debenture-holders and yet secure to the shareholders that value which I am advised and believe may be still considered to remain in their holdings. I see no reason to doubt that I shall succeed in this, and that ultimately the debt of £3,000 and upwards, and also the nominal capital exceeding £20,000 which I as liquidator hold in the New Zealand Electrical Syndicate will become valuable assets, but in the meantime the result of the disputes referred to has been so far adverse to the present realisation that the cash assets in New Zealand, which, when I entered upon my liquidation, I hoped to have received, prior to this date, still remain in that country, and there is no prospect of immediate remittance. I will now recall the attention of the contributories to the resolution which was passed at the meeting held on August 1, 1894, authorising me to enter into an arrangement with Easton, Anderson, and Goolden, Limited, for the sale to that company of the Company's plant, machinery, stock-in trade at the price of £12,500, payable as to £5,700 part thereof in cash, and as to £6,500, the balance thereof in 680 shares of £10 each, fully paid, in Easton, Anderson, and Goolden, Limited. I informed the gentlemen who were present at that meeting that I was advised not only that the offer was highly beneficial, but that the cash paid was alone greater than I could have expected to receive at a break-up price. The shares, therefore, were taken for what might be their value, it being well known that there was no market for them at that time, and that they were not earning dividend. The solicitors acting in this liquidation are also solicitors for Easton, Anderson, and Goolden, Limited, and they have procured for me from another client of theirs an offer of 5s. in the £ for these shares—that is, £1,700. There is no market for the shares, and I am not able to say anything as to their intrinsic value, but I do know that there is a very considerable issue of debentures in front of them. It is only therefore from those who are in some way interested in the Company that an offer can be obtained. If this meeting authorises me to accept that offer, I shall, after discharging the expenses of the liquidation to date, apply the moneys obtained in further reduction of the £2,500 which remains owing on the security of the first debentures, as it is obvious that until those first debentures are discharged there can be no payment to the unsecured creditors. In conclusion, I can only say, gentlemen, that while I do not take at all a despondent view of the ultimate realisation of the assets of this Company, I cannot hold out to you the hope that funds will reach my hands available for dividend at any early date.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY, LIMITED.

On Tuesday the half-yearly general meeting of the above company was held at the offices, Old Broad-street, Admiral Sir G. H. Richards occupying the chair.

The **Chairman** said that the dividend which they had declared for a great many years at this period of the year—12s. per share, or at the rate of 10 per cent. per annum—would be paid to-day. The present year had not been a good one for the manufacture of telegraph cables, which, however, were not articles of every day use, and they did not look forward every year to obtain any very great telegraph work. It was, however, not at all an unusual thing occasionally to have a slack time in the manufacture of submarine cables. As regarded their general trade—the guttapercha work—it had been slightly better than it was at the same time last year.

No resolution was submitted to the meeting beyond the customary vote of thanks.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald, Middlesex; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the directors, with abstract of accounts for the half-year ending June 30, 1895, to be submitted to the half-yearly ordinary general of the Company, to be held at Winchester House, Old Broad-street, in the City of London, on Monday, July 29, 1895, at 3 p.m.:

The receipts from all sources for the past half-year have amounted to £24,401. 15s 8d., and the cost of working has been £15,019. 16s., leaving a profit of £9,381. 19s. 8d. Inclusive of the balance brought forward from December 31 last, the net revenue account shows an aggregate total of £10,379. 8s. 8d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £6,420. 16s. 2d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of 1¼ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £964. 11s. 2d. to be carried forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:

Half-year ended	Number of passengers (exclusive of season-ticket holders).	Receipts (including season tickets).
Dec. 31, 1890 (11 days)	165.000	£1,568 3 9
June 30, 1891	2,412,343	19,403 6 9
Dec. 31, 1891	2,749,055	19,798 16 6
June 30, 1892	2,813,162	20,931 4 2
Dec. 31, 1892	3,117,602	22,002 17 5
June 30, 1893	3 146,656	22,458 6 9
Dec. 31, 1893	3,093 351	22 067 14 10
June 30, 1894	3,383,154	23,564 10 6
Dec. 31, 1894	3,275,649	23,540 12 4
June 30, 1895	3,113,199	23,711 5 8
Total since the opening of the line	27,269,171	£199,046 18 8

During the first three months of the present year there was a satisfactory growth of the traffic on the line, but the very hot and fine weather of the last three months affected it so much that the increase was not only checked, but a small decrease resulted as compared with the same quarter last year. This was very disappointing, as your directors had confidently looked forward to a considerable increase in the traffic during the past half-year. Considering, however, the very large diminution which has taken place in the traffic of nearly all the railway companies in the kingdom during the same period, your directors are glad that the receipts still show an increase, however small. In accordance with the authority given at the last half-yearly meeting, detailed plans have been prepared for the extension to Finsbury-pavement, and negotiations have been entered into for the purchase of some of the property, but the arrangements are not yet sufficiently completed to enable a report to be made to the shareholders on the present occasion. During the past six months a further sum of £23,200 terminable mortgage debenture bonds has been paid off. The Bill for the extension of time for the works of the Clapham Extension Act, 1890 and for other purposes, received the Royal assent on May 14, 1895. A contract has been let for the construction of the new siding at Stockwell. This, when completed, will enable the work at that station to be carried on with greater economy and convenience.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ille-sur-Tet.—Le Mairie d'Ille-sur-Tet, Pyrénées-Orientales, invites tenders by August 11 for the concession of the electric lighting of the town.

Heywood.—Tenders are invited for relighting the U.M.F. Church, Hopwood, Heywood. The specification may be seen at Mr. Wm. Parker's, 2, Middleton-road, Heywood.

Brussels.—Le Gouvernement Provincial invites tenders by August 2 for a concession for the construction and working of a tramway from the Bourse in Brussels to Koekelberg and Jette-Saint Pierre.

Bradford.—Tenders are invited for the electric lighting of the mechanics' hall and saloon of the Bradford Mechanics' Institute. Particulars can be obtained of Mr. T. C. Hope, architect, 27, Kirkgate, up to 30th inst.

Paris.—L'Administration des Postes et des Télégraphes invite tenders by August 1 for the supply of paper-insulated cables in five lots. Specifications at Rue de Grenelle, 103 (Division du matériel et de l'exploitation électrique, 3e bureau).

Brighton.—The Corporation invite tenders by August 10 for the supply and erection at the electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping. Specifications can be obtained from the town clerk.

Frimley.—The Frimley Urban District Council invite tenders for the supply of 25 new lamps (complete). Particulars can be obtained from the surveyor, Mr. W. J. Hodgson, surveyor's office, Camberley. Tenders must reach Mr. A. M. Kennett, clerk, London-road, Camberley, by 29th inst.

Aylesbury.—Tenders are invited for lighting the public lamps and clock tower within the district for one year from September 1, for the Aylesbury Local Board. The conditions for lighting and all other particulars in connection therewith may be obtained on application to Mr. George Fell, clerk, Aylesbury, to whom tenders must be sent by August 9.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep burning at the same time 2,200 8-c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Romford.—The Romford Urban District Council invite tenders for lighting the public lamps in the town of Romford, as to about 190 of such lamps from sunset to sunrise, during 12 months from September 1. Tenders to include the cost of lighting, cleaning, and repairing, and are to be sent to Mr. Geo. Bailey, clerk, Romford, by 4 p.m. on August 6. A contract and (if necessary) a bond with sufficient sureties will have to be entered into and given by the person or persons whose tender may be accepted. Further particulars may be had on application to the surveyor. No special forms of tender.

Digitized by Google

Salford.—The School Board invite tenders for the installation of the electric light into their new offices, Chapel-street, Salford. Plans and specifications, with forms of tender, may be obtained from Mr. S. V. Clirehugh, A.M.I.C.E., Temple-chambers, Brazennose-street, Manchester, consulting engineer, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Tenders, endorsed "Tender for Electric Light," and addressed to the chairman of the Board, must be sent in by 12 noon on 31st inst. Mr. Ogilvie Duthie, clerk, Town Hall Buildings, Salford.

London, E.C.—Tenders are invited by the Shoreditch Vestry for the erection of a chimney shaft 150ft. high. Specification, with form of tender and bills of quantities, can be obtained from and plans inspected at the office of the consulting engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, from 22nd inst., on payment of £2. 2s., to be returned on receipt of a bona fide tender. Trade union rates of wages and hours of labour to be observed. Sealed tenders, endorsed "Chimney Shaft Tender," to be sent by 4 p.m. on 29th inst. to Mr. H. Mansfield Robinson, clerk, Town Hall, Old-street, E.C.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Wakefield.—The Corporation invite tenders for the supply and erection of the following: section A—boiler-house plant (boilers and fittings, mechanical stokers and engine economiser, feed-pump, injector, etc.); section B—engine-house plant (steam alternators condensers, oil filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tank, etc.); section C—main switchboard and instruments; section D—underground work (cables, junction-boxes, culverts, and trenching, etc.); section E—sub-station fittings (transformers and switchboard, etc.); section F—arc lamps and posts; section G—meters; and section H—overhead crane. Particulars are obtainable from Mr. Robert Hammond, Ormond House, Great Trinity-lane, E.C., on and after August 2, on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders are to be delivered by August 24.

Valletta (Malta).—Sealed tenders will be received at the office of the Receiver-General and Director of Contracts, Valetta, or at that of the Crown Agents for the Colonies, Downing-street, London, until 11 a.m. on August 1, for the supply of materials in connection with the installation of the electric light in the civil and war department buildings in Malta. The materials are comprised under four headings—viz., (1) cables and wires, (2) tools, etc., (3) fittings, fixtures, etc., (4) sundries. Printed forms of tender and of the specifications and conditions may be obtained on application at the above office, Valletta, or at the office of the Crown Agents for the Colonies, Downing-street, London. Each tender must contain the name of the surety whom the tenderer intends to propose for securing the performance of the contract and the payment of the penalties therein established. The surety to be a person residing in the island. No notice shall be taken of any tender not accompanied by a deposit, to be made in the office of the Receiver-General and the Director of Contracts, Valletta, or in that of the Crown Agents in London, of a sum of £5 sterling, to be forfeited to the Government should the party tendering or his surety, in the event of the tender being accepted, fail to appear for signing the contract within three days from the day of the notice given to them to that effect. If the tenderer is not resident in Malta, his tender must contain the name of an agent residing in the island, to whom, in the same tender, power must be given to represent the tenderer in the contract. Any tenders which may be delivered at the Crown Agents' office must be in sealed packets addressed to the "Director of Contracts, Malta—Tender for Materials for Electric Lighting," under cover addressed to the Crown Agents for the Colonies.

RESULTS OF TENDERS.

Brighton.—The following tender (the only one sent in) has been accepted by the Town Council for the supply and erection at the electricity works, North-road, of steam and feed piping, cast-iron storage tanks, feed-water filters, electrically-driven feed pumps, circulation economiser, coal-elevator, and sundries: J. Fraser and Sons, Millwall Boiler Works, London, E., £3,220.

Bedford.—The following tenders have been accepted by the Electric Light Committee for supply and erection of the following plant: (Section A) two water-tube boilers; (B) two 140-b.h.p. double-acting compound enclosed engines; (C) two 90-unit alternators, with stationary armature: Babcock and Willcox, Limited, two water-tube boilers, £960; W. H. Allen, Son, and Co., Bedford, two engines, £906; Siemens Bros. and Co., Limited, two alternators, £1,530; Johnson and Phillips, Old Charlton, three transformers, £225.

London, N.W.—The Metropolitan Asylums Board have accepted the tender of Thorpe and Waring, at the sum of £554, for wiring for electric lighting the five new wards and other buildings now in course of erection at the North-Western Hospital, according to plan and specification prepared by Prof. Ayrton, consulting engineer. The following is a list of the tenders received:

Thorpe and Waring	£554	0	0
Electrical and General Engineering Company, 86, Leadenhall-street	649	0	0
T. Matthews, Islington	650	0	0
Waring and Sons, 181, Oxford-street	688	15	0
Fowler, Lancaster, and Co., Birmingham	859	15	0
Benham and Sons, Wigmore-street	870	0	0
Paterson and Cooper, Victoria-street	895	0	0
J. Sax and Co., Ridgmount-street	944	8	9
J. C. Howell, Limited, Queen Victoria-street	981	16	4
London and Lancashire Electrical and General Engineering Company	1,050	0	0
Miller and Woods, Gray's-inn-road	1,070	0	0
Sharp and Kent, Victoria-street	1,098	0	0
Tayler Smith Electric Company, South Moulton-street	1,124	0	0
Roger Dawson, Limited, Berners-street	1,140	0	0
H. Tyler and Co., Whitecross-street	1,340	0	0
V. G. Middleton, Westminster	1,440	0	0
Vaughan and Brown, Kirby-street	1,557	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,078.

Appointment Vacant.—The Islington Vestry require an electrician at a salary of £2. 10s. per week. Particulars will be found in our advertisement columns.

Cuba Submarine Telegraph Company.—The directors have resolved to recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 21st inst. amounted to £1,226, as compared with £1,034 in the corresponding week of last year, being an increase of £192.

Rotherhithe.—The Vestry have decided to offer no objection to the application of the Capital and Counties Electricity Supply Company for a provisional order to authorise the company to supply electricity in the parish.

Ceylon.—Should Mr. Mathews's scheme in connection with the Colombo electric tramways scheme fall through, it is reported, says *Indian Engineering*, that Messrs. Bounstead and Co. are ready to put forward another scheme.

Lightning Conductors.—We have received from Mr. J. S. Morris, Wardrobe-chambers, 146A, Queen Victoria-street, E.C., an illustrated circular descriptive of his copper-band lightning conductors and his special holdfasts.

Purchase.—The Nalder and Harrison Construction Syndicate, Limited, inform us that they have purchased the stock, plant, and goodwill of the engineering business carried on by Messrs. John Brown and Co. at Perseverance Works, Bow, E.

Bedford.—A meeting of the Town Council has been held at which, on the recommendation of the Electric Light Committee, tenders were accepted for supplying extra engines and electrical apparatus for the extension of the electricity works.

Fenton Bros., Limited.—This Company has been registered, with a capital of £20,000, to acquire the business of Fenton Bros., of Sheffield, Yorkshire, and 22, Bartlett's-buildings, Holborn, manufacturers of silver and electro-plated goods, etc.

Aberdeen.—Last week, through the kindness of Prof. A. B. W. Kennedy, the Corporation's consulting electrical engineer, who defrayed the necessary expenses, the employés of the electrical department of the Aberdeen Corporation had a most enjoyable picnic.

Westminster Electric Supply Corporation, Limited.—The Board have declared an interim dividend for the half-year ending June 30, 1895, at the rate of 5 per cent. per annum, payable on September 1 next to shareholders whose names were on the register on July 24.

Plumstead.—The Vestry have received notices from the Woolwich District Electric Light Company and the Capital and Counties Electricity Supply Company of their intention, severally, to apply to the Board of Trade for a provisional order to supply electricity in Plumstead.

Indian Telegraphy.—The Director-General of Telegraphs in India is in communication with the Government, says *Indian Engineering*, regarding the introduction of Waltair's magnetic induction budget for testing lightning conductors, in the place of the Backnell balance at present in use.

Bournemouth.—The Winter Gardens Committee of the Town Council have reported that they have considered the question of the lighting in the pavilion, and recommended that the surveyor be instructed to report as to any desirable alteration in the lighting arrangements. The report was adopted.

City and South London Railway.—The returns for the week ending July 21 were £831, compared with £839 for the corresponding period of 1894, being a decrease of £8. The total receipts for the half-year 1895 are £2,594, as compared with £2,600 for the corresponding period of 1894, being a decrease of £6.

The Burma Connection Telegraphs.—Work on the Burma-Kentung telegraph line will be proceeded with during the current hot weather, the necessary wire being now sent forward. Unfortunately, says the *Indian Engineer*, the rains begin early in the region to be crossed, but the staff engaged in construction will

Digitized by Google

not be checked in their labours by anything short of wholesale sickness.

Acton.—At the District Council's last meeting it was recommended by the Works Committee that the clerk should write to the Capital and Counties Electricity Supply Company and Limbrey and Co., informing them that the Council intended to oppose their applications to the Board of Trade for a provisional order for lighting the district by electricity. The Council adopted the committee's recommendation.

Agency.—We are informed that Messrs. Francis and Spilsbury, electrical suppliers and agents, of 20, Bucklersbury, E.C., have been appointed special agents for the sale of Messrs. Connolly Bros.' manufactures in the South, East, and West of England (not including London). Messrs. Connolly Bros. are finding an increasing demand for their "Blackley" tape, and also for their specialities in vulcanised rubber-covered wires and cables.

Edinburgh.—At Tuesday's meeting of the Town Council, the Cleaning and Lighting Committee recommended that George-street and streets leading thereto from Princes-street, along with St. Andrew-street, St. Andrew-square, Charlotte-square, and Hope-street, should be lighted with electric light. It was stated that it would cost £600 more than the present gas lighting. On a division, the recommendation was adopted by 12 votes to 9.

Electric Railways for Vienna.—The Secretary of State for Foreign Affairs has received a copy and translation of a notice issued by the Municipality of Vienna calling for tenders for plans, construction, and working of a network of electric railways in and round that city. The tenders must be sent in before the 14th November next. The notice may be seen at the Commercial Department of the Foreign Office, S.W., between the hours of 11 and 6.

The Hermite Process in India.—The Bombay Corporation have considered a memorandum from the Commissioners forwarding a letter from the executive engineer on the question of the use of electrolysed sea-water for flushing sewers, etc., together with an estimate of 60,000 rupees, framed by Mr. Murzban, of the probable cost of providing and fitting up at the Carnac Bunder nightsoil station plant capable of producing 15,840 gallons of Hermite fluid in 12 hours.

Shooter's Hill.—The Ambulance Committee of the Metropolitan Asylums Board reported at the last meeting that as they considered it desirable that the Brook Ambulance Station should be lighted with electricity from the installation of the Brook Hospital, the consumption being checked and apportioned by meter, they had instructed Prof. Kennedy to prepare a scheme and specification for the purpose, which they would submit to the Board in due course.

Ootacamund.—The scheme of the Oriental Electric Light Company, Bangalore, for lighting Ootacamund with the electric light on the maintenance electric supply system by storage power, has met with great success. The whole of the Government House, including the military secretary's and the private secretary's bungalows, are to be lighted by incandescent electric lamps, also the Government House and the Banqueting Hall, and the Guindy Park, as well as Madras, in conjunction with the Government House at Ooty.

Douglas (Isle of Man)—A magnificent park, the latest addition to the Douglas pleasure resorts, is opened to the visiting public by the Isle of Man Tramways and Electric Power Company, Limited, and known as Howstrake Park. It is situated about two miles from Douglas. The grounds are of considerable extent, command probably one of the finest marine and landscape views in the United Kingdom from an eminence of over 400ft. above the level of the sea, and have been laid out by an expert so as to interfere as little as possible with nature.

Limerick.—A special meeting of the Town Council was held on Friday for the purpose of formally adopting an electric lighting scheme for the city. The Corporation are acting under certain compulsion in the matter. The lighting of the city by gas is altogether in the control of the Corporation, and if the members failed to adopt an electric lighting scheme, the Board of Trade had notified they would give the necessary permission to any company seeking to have the Order in Council enforced in Limerick, and such company would consequently be a competing rival with the Corporation.

London, N.W.—In connection with the wiring of buildings at the North-Western Hospital of the Metropolitan Asylums Board, referred to under "Results of Tenders," it was reported at the last meeting of the Board that Prof. Ayrton had stated that for the further work required he would be prepared to accept the following fees: for preparing specification and conditions of contract, 20 guineas; for supervising, testing, and certifying the work, 100 guineas; and for each attendance on the committee, made by request, before the commencement or after the completion of the work, three guineas These terms were accepted.

Derby.—Colonel Walter M. Ducat, R.E., held an enquiry at the Guildhall, Derby, on Wednesday, in respect to certain loans applied for by the Corporation of Derby under the Public Health and Electric Lighting Acts. They included the borrowing of £13,000 for electric lighting purposes, £8 595 for providing a recreation ground, £1,095 for the purchase of property for street improvement, and £943 for sewerage work and other purposes. It was explained by the town clerk that the Local Government Board had already sanctioned £35,000 for electric lighting, and the additional £13,000 now asked for was really to make up the actual expenditure over and above the sum previously granted, which included the erection of additional boilers.

Copper.—Messrs Lewis Lazarus and Sons report, under Wednesday's date: Copper opened firm at a slight advance over yesterday's quotations, and remained steady until towards the close of 'Change, when on free offerings values receded 2s. 6d. per ton, or 1s. 3d. below last night's price. About 800 tons changed hands in the morning at £44. 8s. 9d. and 10s. cash; £44. 10s. and 11s. 3d. for August; £44. 15s. and £44. 16s. 3d. for three months. On 2nd 'Change business was done at 10s., 8s 9d., and 7s. 6d. cash, 11s. 3d. August dates, 16s. 3d., 15s., and 13s. 9d. three months, closing values being £44. 7s. 6d. cash, £44. 13s. 9d. three months Settlement price, £44. 10s.

Cambridge.—At the last meeting of the Town Council the Paving, Drainage, and Lighting Committee reported that, in accordance with the resolution of the Council of the 20th ultimo, they had reconsidered their report with reference to the repair of the paving round the street boxes belonging to the Cambridge Electric Supply Company, with the result that they instructed the town clerk to inform the company that the committee were of opinion the company were liable for the repair of the paving in question, and that the Corporation could not, therefore, undertake to relieve them from their responsibility. The committee now asked the Council to confirm their action in the matter. Councillor H. M. Taylor proposed that the action of the committee be approved. This was seconded by Councillo W. F. Taylor, and carried.

The Ceylon Telephones.—It seems, says the *Times of Ceylon*, that there is very little doubt that by the commencement of the new year, the telephone system in Colombo will be in the hands of the Government. Whether that will be brought about by the existing private system being taken over by the Government or not is not settled. The alternatives seem to be these: If the various telephone companies working in the East can influence the Secretary of State so as to get the Eastern Colonies and India to take over the existing systems, that will be done in Ceylon; but should this action on the part of the Secretary of State not be brought about, then the local Government will resort to local measures and in the case of Ceylon they will establish for themselves a new exchange with a more modern system of telephoning than that which Colombo has at present.

Brighton.—At the Town Council's last meeting the Lighting Committee reported that in response to the advertisement for the supply and erection of steam and feed piping, feed pumps, economiser, water purifier, tanks, coal-elevator, and sundries required at the electricity generating station, they had received only one tender—viz, from Messrs. John Fraser and Son, of Millwall Boiler Works, who offered to do the work for the sum of £3,220, and they recommended that this offer should be accepted. Councillor Stafford proposed the adoption of this recommendation. He observed that the committee were not at present prepared to recommend the acceptance of a tender for the supply of the condensers air-pumps, air-pipes, etc. There was so much detail that they had not been able to get the matter ready. The committee were, however, anxious to prepare for the work, and they hoped to have the confidence of the Council in what they now proposed to do. The report was agreed to.

Embezzlement.—On Saturday at Bow-street, Wm. D. Boddy, 38, of Shirland-road, Maida-hill, was charged before Mr. Lushington with embezzlement. Mr. Harry Wilson (Wilson and Wallis), who prosecuted, stated that the prisoner was a cashier in the employment of the Charing Cross and Strand Electricity Supply Corporation. On June 14 Mr. Robbins, steward to the Duchess of Marlborough, paid to Mr. Thomas, a clerk in the employ of the same corporation, £26. 19s 3d. This money was handed to the prisoner, but he neglected to enter it into his books or to pay it into the bank. The matter came to the knowledge of Mr. Seal, the secretary. He questioned the prisoner, who made several false statements. A meeting of the directors was subsequently held, and the prisoner admitted having received two other sums for which he had not accounted. He called upon Mr. Seal on Friday night and volunteered to accompany him to the police station. Evidence in support of this statement having been given, Mr. Wilson said the prosecutors did not wish to press the charge. Prisoner pleaded guilty. Mr. Lushington said that it was a very bad case, and sentenced him to four months' hard labour.

Globe Telegraph and Trust Company.—The report of the directors of this Company for the year ended July 18 states that the net revenue of the Company, after deduction of expenses, amounts to £179 465, and makes, with the balance of £527 brought forward, a total of £179,992. From this amount there has been distributed the sum of £123,361 in interim dividends, leaving an available balance of £56,661. The directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares and of 3s. 3d. per share on the ordinary shares, making, with the previous distributions, a total dividend for the year of 6 per cent., less income tax, upon the preference and 4½ per cent. net (against 4½ per cent. for the preceding year) upon the ordinary shares and carrying forward a balance of £1,238. Since the last meeting a further sum of £38,592, resulting from the paying off of the Direct Spanish Telegraph Company's 6 per cent. debentures has been invested as follows: 520 ordinary shares in the Direct Spanish Telegraph Company, 102 certificates in the Submarine Cables Trust, 1,135 shares in the Western Union Telegraph Company, 400 shares in the Cuba Submarine Telegraph Company. The remainder will be invested in suitable securities.

London Fire Alarms.—The Fire Brigade Committee of the London County Council on Tuesday reported that of the eight fire-alarms in connection with the New Cross fire-engine station, the

Digitized by Google

provision of which was authorised by the Council on July 24, 1894, seven had been fixed, but as the Post Office had been unable to obtain the necessary wayleaves for the remaining one proposed to be fixed in Pepys-road, the committee had arranged that it should be fixed at the junction of St. Peter's-road with Brockley-road. The result will be that the annual charge for the eight fire-alarms would be increased by £3. 10s. The committee have sanctioned the fixing of telephone apparatus to the fire-alarm in Marshalsea-road, Southwark, where a fireman is stationed at night with a fire-escape. This will enable the fireman to receive from the engine station in Southwark Bridge-road an order by telephone to answer any call received at the station from another fire-alarm near which there is no fire-escape. It is expected that this arrangement will enable fire-escapes to arrive at fires more rapidly than is now sometimes the case, and the committee hope to be able after the recess to report what would be the cost of adding telephone apparatus to fire-alarms at other escape stations. The annual charge for the apparatus in the case referred to will be £3. 10s.

The Embankment.—On Tuesday the Highways Committee of the London County Council recommended that they should be authorised to take all necessary measures for establishing, at a cost not exceeding £16.590, electric lighting for the Victoria-embankment and the Waterloo and Westminster Bridges (but exclusive of the embankment gardens) authorised by the Council's (General Powers) Act, 1893; and that for this purpose the committee be authorised to obtain tenders and to enter into contracts on behalf of the Council. The full terms were given in our issue of 12th inst. The following amendments were moved: By Mr. Thornton (seconded by the Earl of Onslow): "That the Highways Committee be instructed to obtain reports from the engineer and the chemist upon the question whether the lighting of the Victoria-embankment and the bridges could be improved by the substitution of incandescent burners for those at present in use." By Mr. E. White: "That the recommendation be referred back to the committee with instructions to ascertain and report what is the cost of the present lighting, what would be the cost of incandescent gas lighting, and what would be the cost of electricity supplied by a company." By Mr. Benn: "That the recommendation be referred back to enable the committee to bring up a report as to the cost of including in the estimate the lighting of the Victoria-embankment gardens." The whole of the amendments were agreed to.

Anglo-American Telegraph Company.—The report of the directors for the half-year ended June 30 last states that the total receipts, including the balance of £485 brought forward from the last account, amounted to £141,715. This sum, however, is subject to revision, as the financial result of the judgment given in favour of this company against the Paris and New York Telegraph Company cannot yet be determined. The traffic receipts show an increase of £9,382 as compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, etc., as shown by the revenue account, amounted to £55,384, being a decrease of £332. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £74,331. One quarterly interim dividend of 10s. per cent. on the ordinary stock and of £1 per cent. on the preferred stock was paid on May 1, 1895, absorbing £35,000, and a second quarterly dividend of 11s. per cent. on the ordinary stock and £1. 2s. per cent. on the preferred stock, amounting to £38,500, will be paid on August 1, 1895, leaving a balance of £831 to be carried forward to the next account. The company's repairing s.s. "Minia" has been employed during the past half-year in the repair of the 1874 cable, broken off the coast of Ireland, and of two of the cables connecting Newfoundland with Cape Breton.

Direct United States Cable Company.—The report of the directors for the six months ended June 30 states that the half-year's revenue, after deducting out-payments, amounted to £37,653, as compared with £34 843 for the corresponding period of 1894, being a difference of £2 809 in favour of the half-year under review. The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £18,909, leaving a balance of £18,744 as the net profit of the half-year, making, with £1,807 brought forward from the previous half-year, a total of £20,552. For the corresponding period of 1894 the working expenses and other payments amounted to £18,750. Three quarterly interim dividends, amounting to £18.213, have been declared and paid during the financial year, and a final payment of 2s. per share is now proposed, making, with the three interim dividends, 2 per cent. for the year, being a total distribution of £24,284. After transferring £7,000 to the reserve fund account, the balance of £1,410 on the revenue account is proposed to be carried forward. During the period under review repairs of the Company's cables have cost £1,730. This amount, together with the £673 written off the buildings account, Ballinskelligs, in respect of old buildings pulled down, have been debited to the reserve fund account, the balance of which, with the addition of interest, profit, and amount transferred from revenue account, now stands at £298,369.

The Electric Lighting of Calcutta.—The following is the statement of objects and reasons appended to the Bill to facilitate and regulate the supply of electricity for lighting and other purposes in Calcutta: The Government has at present no power to grant a license or provisional order for the supply of electricity. The Indian Telegraph Act, 1885, under which licenses have been granted to telephone companies, deals only with appliances for making communications by means of electricity. Act No. XIII. of 1887 is an Act to provide for the protection of person and property from the risks incident to the supply and use of electricity, but it does not provide for the grant of licenses. Nor does it provide for many other matters which are essential for the protection of contractors from undue interference or restraint, and the public from excessive charges and undue preference. These matters cannot be satisfactorily arranged without legislation. The object of the present Bill is to enable the Government of Bengal to grant licenses for the supply of electric lighting within any part of Calcutta The Bill closely follows the Electric Act of 1882 (44 and 45 Vict., chap. 56), but as it is intended to empower the local Government to grant licenses only, every reference to "provisional orders" and "special Acts" has been omitted. The local Government is substituted for the Board of Trade throughout. The definition of Calcutta is taken from the Calcutta Municipal Act of 1884, but power is given in the Bill for extending its provisions to the Howrah Municipality. The necessary powers for breaking up streets, etc., for the purpose of supplying electricity within the area specified in the license have been adopted for the most part from the Gasworks Clauses Act of 1871.

Ipswich.—At the last meeting of the Paving and Lighting Committee of the Town Council, Mr. E. A. Paris, of the County of London and Brush Provincial Electric Lighting Company, Limited, attended and stated that his company had made an application for a provisional order for supplying electricity in Ipswich and asked the consent of the Corporation. In most towns the corporation had taken up the supply of electricity on their own account, but in others they had given their consent to the grant of a provisional order to a company under certain conditions. The company he represented were willing to accept a reasonable condition as to power on the part of the Council to purchase at any time during the 42 years, or, as they would prefer, to take an order pure and simple. The Act of 1888 gave a corporation power at any time to start electrical works, notwithstanding that they might have given consent to a provisional order being granted to a company, and that was the strongest lever there could be against any undue price being asked by the company if the corporation were willing to buy the undertaking. On the other hand, some councils felt it desirable to have a definite agreement as to the terms on which they might purchase at any time. What was known as the Oxford clause had been regarded as fair; under it the corporation would be entitled to purchase on terms of capitalising the actual outlay of the company at 5 per cent. Mr Josselyn asked whether the company was not a branch of the Brush Company, which had obtained an order and had failed to carry out the undertaking. Mr. Paris said the Brush Company was a manufacturing company, and had not capital sufficient to undertake the supply of electricity. The present company was formed for the purpose of supplying electricity, and had orders for Dover, Bournemouth, Wandsworth, St. Luke's, Camberwell; St. Olave's, Southwark; and Richmond. They had a capital of £200,000 or £300,000. Conversation followed among the members of the committee on the point whether the Electric Light Committee of the Corporation was still in existence as a standing committee, or whether, after the report presented at a recent meeting, it was not *functus officio*. It was clear that the Paving and Lighting Committee had no authority in the matter, and the Chairman recommended Mr. Paris to make a formal application for the consent of the Council, before whom it would come in the regular way.

Halifax.—Mr. F. H. Tulloch, M.I C.E., an inspector under the Local Government Board, has held an enquiry at the Town Hall, Halifax, with respect to an application made by the Halifax Town Council for sanction to borrow £10,000 for electric lighting purposes. Amongst those present were the Mayor (Alderman M. Booth), Alderman S T. Midgley, Alderman J. Brook, the town clerk (Mr. K. Walton) and other members of the Town Council. The Town Clerk said that in 1892 the Corporation obtained a provisional order empowering them to erect works for the supply of electricity. They obtained the permission of the Local Government Board to borrow £30,000 for that purpose. They had, since, however, found that they would require an additional £4,947 to complete the original scheme, and £5,000 for the purpose of extensions. They had actually expended £34,947, whereas the original estimate was only £26,100. In the original estimates the Corporation proposed to utilise some land that belonged to them, but after further consideration it was decided that a more convenient site should be obtained, which was done at a greater cost than the original estimates provided. Alderman Brook pointed out that for mains and services application was made only for £500. As the committee had now decided to extend their mains to Skircoat, he suggested that this figure be doubled. The Inspector agreed to this application. In reply to Alderman Tattersall, the Town Clerk said that Alderman Brook was quite in order in making his suggestion without having first consulted the Town Council. The works included still came within the £5.000 the Corporation had authorised him to apply for. The Inspector asked how it was that the electric light building had cost three times the original estimate. The Town Clerk said that the original plan was for the conversion of buildings situate on the first site. On the new site new buildings had to be put up entirely. They had entered into a contract for a new engine, which would be required for winter, as they were unable to wait. That was the only contract entered into that would have to be met out of the money they were now applying for. Mr. Wilmshurst, engineer to the works, in reply to the Inspector, pointed out that Skircoat was not within the Corporation's compulsory area. It, however, formed the chief

Digitized by Google

residential part of the borough. Mains had been laid throughout the compulsory area, with the exception of Lee Bridge and Dean Clough, where they had no customers. The inspector afterwards visited the electric light works.

Harrow.—Mr. Oliver A. Saunders, of Harrow, writes to a local paper as follows: "It has been pointed out to me that, although a lawyer or other man of business will readily appreciate the mischief of allowing a monopoly of the supply of electricity to be established in private hands in Harrow, yet some explanation is necessary to place the matter clearly before the ratepayers, who may otherwise imagine that the monopoly will not affect themselves, since no local company can be expected to produce electricity at such a price as will bring it within their reach. The ratepayers last year wisely refused to accept the late Board's scheme, which involved the production of 43,000 units of electricity for street-lighting, at the nominal charge of about 3d. per unit, instead of 8d., thereby imposing a dead loss of over £900 a year on the town, as producers, under that item alone. It suits the purpose of those who are now seeking to obtain a monopoly to represent that this refusal justifies them in saying that the provisional order is useless to the town, and may be properly handed over to a company, if the ratepayers are relieved of the cost of obtaining it, a cost which is represented by a temporary annual charge of about £20 a year. The concession, it is true, probably has little direct value in itself, but its indirect value to an electric lighting company would consist in the power which they hope to acquire thereby of excluding competition, and thus maintaining the price of electricity at the high level at which alone a local company can afford to produce it. When the time comes (and it is surely not far off) that electricity can be brought from the coalfields to our doors at a price which will bring it within the reach of every ratepayer, then the ratepayers would fully realise the mistake of allowing the town to be saddled with a monopoly for the benefit of a small section of the community. To create such a monopoly is, in fact, merely another method of throwing upon the ratepayers a part of the very same risk which they emphatically repudiated last December, since it would impose a prospective tax upon cheap electricity in order to secure a return upon capital which is to be expended exclusively for the benefit of a few individuals. If cheap electricity does not come the monopoly will be useless, if it does come the monopoly will impose an unfair burthen on the poorer ratepayers; in neither case can the creation of such a monopoly be justified. The provisional order has been obtained at the expense and for the benefit of the whole community, and is available by way of license for the use of any ratepayers who wish to supply themselves or their neighbours with the electric light, but the Electric Lighting Act of 1888 clearly provides that no monopoly shall be created by the grant of a provisional order without the consent of the local authority; and it is a manifest betrayal of trust for a local authority to attempt to deprive the poorer inhabitants of this protection by appropriating the benefit of the provisional order for a few wealthy ratepayers, to whom the cost of electricity is a secondary consideration. Happily, we now have an opportunity of applying to the Board of Trade to protect us against this injustice. A copy of the memorial awaits signature at Mr. Provost's shop, and further copies can be there obtained by any ratepayer who is willing to assist in obtaining other signatures Such assistance is urgently needed."

PROVISIONAL PATENTS, 1895.

JULY 15.

13550. **Improvements in dynamo-electric machinery.** Frederick Henry Royce and Ernest Alexander Claremont, Electron, Cavendish-road, Chorlton-cum-Hardy. (Complete specification.)

13564. **Improvements in and relating to electric regulators.** William Vernon Bonsor, 126, Gladstone-road, Wimbledon, London. (Complete specification.)

13573. **Improvements in multiple switches for telephone exchanges.** Franz Stock, 46, Lincoln's-inn-fields, London. (Complete specification.)

JULY 16.

13618. **Improvements in or relating to electrically-actuated mechanism.** Septimus Felix Beevor, 433, Strand, London.

13619. **Improvements in and connected with underground conductors for electric railways and tramways.** Jasper Wetter, 433, Strand, London.

13635. **Improvements in electric gaslighters.** Harry Graham Grier, Albert Gleaves Grier, and Alfred Samuel Hottle, 47, Lincoln's-inn-fields, London. (Complete specification.)

13636. **Improvements in electric signalling apparatus.** Lucien Stephen Crandall. 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 17.

13663. **Improvements in connecting plugs and switches for electric lighting and power purposes.** Julius Peschek, 8, Great Portland-street, London.

13670. **Improvements in and connected with electrical incandescent lamps.** Henry Cooper, 70, Market-street, Manchester.

13689. **Improvements in the manufacture of incandescent electric lamps.** Alfred Vincent Newton, 6, Bream's-buildings, Chancery-lane, London. (Alfred Nobel, France.)

13695. **Improvements in portable electrical railway carriage and other roof lamps.** Henry William Headland, 77, Chancery-lane, London.

13702. **Apparatus for regulating or measuring electric currents.** Henri Pieper (fils), 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 18.

13727. **Improvements in or relating to combined alternators and dynamos and the like, and to the distribution of electricity thereby.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

13730. **Improvements in and relating to primary batteries.** Walter Rowbotham and Hymen Levetus, 45, Southampton buildings, Chancery-lane, London.

13760. **Improvements in and in connection with the working of electric tramways on the accumulator system.** Charles Rayleigh, 191, Fleet-street, London.

JULY 20.

13872. **Improvements in or connected with steam alternators and the like and in the mode of operating them for the distribution of electricity.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

13900 **Improvements in galvanic batteries.** Ralph Wardlaw Gordon, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Section 103, January 31, 1895, being date of application in United States.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1894.

15353. **Electric motors.** Routledge.

15737. **Phonographs.** Edison-Bell Phonograph Corporation, Limited, and Wilkinson.

16131. **Electric signs, etc.** Hawksey and Lamb.

16331. **Electric organs.** Harrison.

1895.

1797. **Electric lamps.** Stiens.

8393. **Electric lighting of railway vehicles.** Moskowitz and others.

8394. **Dynamos.** Moskowitz and others.

NOTES.

Cable Communication with Caldy Island.—The telegraph ship "Monarch" was in Tenby Roadstead on Monday awaiting a favourable opportunity to lay a cable connecting Caldy Island with the mainland.

Personal.—King Alexander of Servia has conferred upon Prof. H. J. Spooner, the director of the Polytechnic School of Engineering, a Knight Commandership of the Royal Order of St. Sava, as a recognition of Mr. Spooner's labours in the cause of science.

Electricity in the Navy.—H.M.S. "Powerful," which has been launched from the yard of the Naval Construction and Armaments Company, Barrow, is lighted throughout with electricity, having about 900 incandescent lamps and six powerful search-lights.

Books Received.—We are in receipt of the *English Illustrated Magazine* for August, which contains a good variety both of literary matter and of illustrations.—Messrs. Crosby Lockwood and Son send us "The Management of Dynamos," by Mr. G. W. Lummis-Paterson.

Post Office Telegraphs.—Mr. Chas. E. Stuart, controller of stores, General Post Office, writes: "I beg to inform you that the offices of the Controller of Stores (Postal Telegraphs), hitherto situated in Telegraph-street, have been removed to the General Post Office, St. Martin's-le-Grand."

Electric Traction in Spain. — The municipal authorities of Barcelona are actively arranging for the introduction of electric traction into their city. They have appointed a commission of 30 members to examine and report upon the systems adopted in Marseilles, Genoa, and Milan.

The Electric Light in Spain.—*El Imparcial* reports the inauguration of the electric light in another Peninsular town, Orense, which, situated in Galicia, and the capital of the province of Orense, has a population of 15,000. There were great celebrations in honour of the introduction of the popular illuminant.

Electricity in Russia.—The Russian naval authorities have appointed an electrical engineer for the port of Cronstadt, who will take the rank of a staff officer and receive a salary of 3,200 roubles, or £500, a year, and whose first duty will be to organise a system of electric deck-lighting for the Tsar's Baltic fleet. It is stated that a similar post already exists at Nikolaiev.

Welsh Jocosity. — The following paragraph has appeared in the *South Wales Daily Post*: "One of the reasons given for delay in introducing electric lighting into Swansea is the great distance between the poles which support the lamps, the present arrangement of lamp-posts being found very convenient by gentlemen returning home after a 'smoker' or banquet."

Purification of Acetic Acid by Electricity.—Crude acetic acid is usually purified by distillation in copper vessels, a resulting by-product, acetate of copper, being very noxious, especially in the dyeing industry, when alizarine red is being produced. A M. Eremin has, it is stated, invented a process of electrical refining which is giving great satisfaction in Russia.

Telegraphy in British North Borneo.—A telegram has been received from the Governor of British North Borneo to the effect that 90 miles of the telegraph across the country have been completed and are open for communication with the coast, and it is expected that, if not unduly hindered by the rainy season, the line will be finished for through communication to Sandakan by January next.

Lighthouse Communication.—The Central News says that a deep-sea cable, connecting the mainland near Browhead to the Fastnet Rock Lighthouse, has just been completed for the Board of Trade. The purpose of the cable is not only to signal and report all passing vessels, but to give them their orders at sea. The scheme is looked upon as one of considerable importance to shipowners and mariners.

The Galatz Tramways.—With reference to the paragraph headed "Corruption?" in our issue of July 12, page 29, the French Consular Department officially announces that the contract for the construction of the electric tramway in Galatz has been let to the Société Charles Georgi, of Paris, which company is already the concessionnee of the gas and electric lighting of that Roumanian town.

"Electrocution" of Dogs.—Hereafter all stray dogs caught in Brantford, Ont., will be electrocuted. The victim is fitted with four leather boots with metallic soles; a piece of wet sponge is fitted in the interior of the boot, and a copper wire connected with the street-lighting system is attached to the metallic soles. A policeman holds the dog by a rope around the neck, and a fireman acts as executioner. A switch in the fire-hall is turned on, giving a current of 1,700 volts.

Junior Engineering Society.—We have received the *Transactions* of this society (now called the Institution of Junior Engineers) for the thirteenth session, 1893-4. The papers read include one by Mr. A. H. Dykes on "Electromotors," and among the works visited and described are the Cardiff electric light works, and the Great Eastern Railway Company's electric light works, London. In addition, visits were paid to the engineering laboratories of the Battersea Polytechnic and University College, London.

Japan's Import of Dynamos.—According to the latest statistics available, we have forged ahead of Germany in respect of the supply of dynamos to Japan. In 1892, the figures for the Fatherland, machines to the value of 73,741 yen, were far in advance of those which could be claimed by this country and the United States; but in 1894 the import from Germany was valued at 18,120 yen only, compared with the respective amounts of 49,322 yen for Great Britain, and 145,200 yen for North America. The yen is worth about 3s.

Electric Cranes.—The officers and engineers of the Portuguese warship "Vasco da Gama" have specially visited the Southampton Town Quay to inspect the working of the electric cranes erected there some time since. They were received by Mr. W. Bowyer, the wharfinger, and Mr. J. E. W. Aldridge, electrical engineer, and shown the cranes in operation. These two cranes are the only jib cranes of their size and construction in this country. Great interest was evinced in the matter by the officers, and they expressed their admiration at the manner in which they were manipulated with working loads.

Trans-African Telegraphy.—Slatin Pasha has been interviewed, and on being asked as to how the Trans-African telegraph scheme was likely to fare in the Sudan, said: "What is the necessity for the line? It is impossible to get a telegraph across Africa until the whole of the continent is under European, Ottoman, and Egyptian control. When this is accomplished, then it is time enough to talk of a telegraph. Mr. Rhodes's scheme, as far as the Sudan is concerned, is an impossibility until the Dervishes are wiped out. To make arrangements with or subsidise them is quite out of the question."

Digitized by Google

Electric Headlight for Cyclists.—An electric headlight for cyclists has been invented by an American firm. A small storage battery of about eight ampere-hours' capacity is carried on the bicycle or in the rider's pocket, and a body wire leads from it to the terminal points on the back of the cap. The lamp in front is detachable and weighs only about 1½oz. In this simple manner a true searchlight is obtained, because the light is always focussed in the same direction that the rider looks, and being on the visor of the cap the eyes are protected from the light, which illuminates the way most satisfactorily.

Gas and Electricity.—The *Semaine Electrique* remarks that it has often defended the cause of the union of gas and electricity. After Ostend, it says, we have Galatz, Braila, Szegedin, Alba, and Arad, in which the companies who have obtained the necessary concessions have engaged to supply both illuminants and produce their electricity by means of gas-engines. Moreover, in some of the towns enumerated the motive power of the tramways will be generated under the same conditions. Our contemporary adds that the shareholders of the Société Internationale de Gaz ou d'Electricité, at the head of which is M. Somzée, will not regret embarking in an enterprise which cannot but prove a source of considerable profit to them.

Telephone Charges in France.—French papers grumble that the subscription to the telephone in France still costs 400f. a year, especially, they argue, in view of the comparatively inefficient service which is provided by the State. Reference is made to the charge of 150f., plus a franc for interurban communication, current in Belgium, and to the rate of 40f., "everything included," in Switzerland. The papers suggest that the Government should apply the same principle to telephonic communication that it has used in the postal service—namely, effect a reduction in the charges—and thus secure a considerably extended personal subscription. We have the same complaint in England, but we adopt the still more unfavourable comparison of Sweden.

Trolley Parties in Philadelphia.—Trolley cars are being largely used in the United States for pleasure parties who hire special cars and go for long runs into the country. In an article on the subject of this method of amusement in Philadelphia, a New York paper states that "such parties have become a fashionable craze among 'stay-at-homes' and 'can't-get-aways,' and people of the most respectable caste join in the popular movement. The popularity of trolley locomotion and mid-summer night sociables on wheels forms a remarkable contrast to the warlike opposition that was waged against the introduction of overhead wire transit in Philadelphia. When it came it met with a wail of opposition. Now, if it should be taken away from us the bottom would fall clean out of the old City of Brotherly Love, and it would fairly collapse."

Electric Motors in Gasworks.—At the meeting of the Institution of Mechanical Engineers in Glasgow on Tuesday, Mr. Andrew S. Biggart, of Glasgow, read a paper on "Hydraulic Stoking Machinery and Labour-saving Appliances in Modern Gasworks." In the course of the discussion that followed, Mr. Head said that the ingenuity displayed in the charging and discharging retorts had been very much the result of the labour troubles of some two or three years ago. He would like to know whether Mr. Biggart had turned his attention to the substitution of electric means for hydraulic power in this kind of machinery? It seemed to him that this bore a resemblance to an overhead travelling crane, and in America electricity had very much taken the place of other mechanical appliances. Mr. Biggart, in reply, said that with regard to the electric power, that was a matter which had received attention, but the objection to such power was this, that they would require to introduce revolving machinery and shafts.

Effect of Volcanic Action upon Earth Currents. Signor L. Palmieri, of the Vesuvius Observatory, has taken observations during the past six years upon the action of earth currents on a telegraph line extending between the observatory and Resina. He has found that when Vesuvius is inactive, or during periods of minimum activity, the earth currents flow upward, irrespective of the azimuth at which the wire is placed, increasing and diminishing inversely as the activity of the volcano. When this activity reaches a certain point the currents cease, and if the volcanic action still further increases the earth currents begin flowing downwards, increasing with the activity of the crater. The experimenter, therefore, concludes that in the case of wires inclined to the horizon and out of the reach of volcanic interference the earth currents flow upward in whatever azimuth the wires are placed.

The Lyons Electrical Power Project. — The Société Lyonnaise des Forces Motrices du Rhône, a correspondent says, recently opened a competition with the view of obtaining the best project for utilising, at the Canal du Jonage, the water power of the Rhone to the extent of 20,000 h.p., with the object of supplying the city of Lyons with electrical energy for lighting and industrial purposes. The jury which was called upon to deliver its judgment upon the various plans selected, and which consisted of Prof. Galileo Ferraris, of Turin, and MM. Eric Gérard and R. V. Picou, has now awarded the first prize of 10,000f. to the joint project of the Compagnie de l'Industrie Electrique, of Geneva and Paris, and Messrs. Escher, Wyss, and Co., of Zürich, the former firm being responsible for the electrical portion of the scheme and the latter firm for the hydraulic part. The second premium of 5,000f. was obtained by Le Creusot; the third, of 3,000f., by the Société Alsacienne; and the fourth, of 2,000f., by L'Electro Mécanique.

The Telephone Service.—We have already given the report of the Select Committee of the House of Commons on the telephone service. This report, together with the minutes of evidence, is now issued as a bulky Blue-book of 370 pages, which can be purchased by those who require it. However, the proceedings of the committee were duly recorded, though not at such inordinate length, in the columns of the *Electrical Engineer* at the time. The committee, we may remind our readers, comprised the following: Captain Bagot, Mr. Baird, Mr. Benn, Sir Charles Cameron, Mr. John Ellis, Sir James Fergusson, Sir Julian Goldsmid, Sir John Gorst, Mr. Grant Lawson, the Solicitor-General, Mr. Arnold Morley (chairman), Mr. Moulton, Mr. Snape, Lord Stanley, and Mr. Tully. If another committee be appointed, as the old committee recommend, many of these gentlemen will perforce be absent from it, owing to their having been "chucked" by their constituencies, for with respect to a party which once existed one must ask with Hans Breitmann, "Vare is dat bardy now?"

The Renault Dry Cell.—The *Bulletin International de l'Electricité* of July 22 contains an account of the "elegant and very practical" dry cell invented by Prof. Renault: "It is composed of a vessel of agglomerated retort carbon, in the bottom of which is chromic acid combined with gelatinous silex, which possesses the remarkable property of absorbing 60 times its volume of water. This composition constitutes the active part of the cell. This portion is insulated from the

Digitized by Google

rest of the apparatus by a porous earthenware disc, supporting a spiral of zinc containing in its volutions gelatinous silex only. The method of operating will easily be understood. The chromic acid acts upon the zinc in passing across the porcelain disc and produces the current. The advantages of this cell lie in the considerable surface development of the carbon of which the vessel is composed and of the helical zinc, thus giving a maximum of surface with a minimum of encumbrance. This apparatus, then," the journal adds, "is capable of furnishing considerable energy from a small volume."

Electric Fountains.—The electric fountain at the Cotton States and International Exposition, which has been devised by Mr. Luther Stieringer, the consulting electrical engineer to the exhibition authorities, is attracting much attention in America. The design is that of a twin fountain, rising from an islet in the centre of the great basin, immediately in front of the machinery hall. The island, which forms the groundwork for the base of the fountain, and covers the operating-chamber, is 100ft. long and 50ft. wide. There are 19 orifices, each with from seven to ten jets. The electric lights used under each opening to project the beam of light through the water are of 250,000 c.p. each. The four forms of water used are the solid stream, the geyser, the spray, and the fog-bank. The highest jets will rise over 100ft. from the basin of the lake. The fog-bank is to be produced by steam, condensed by means of spray. The four forms will be used alternately in various ways. The streams and geysers will be interspersed with circular pipes throwing jets in the form of wheat sheaves.

The Disturbance of Electrical Instruments.—In view of the objection which has been raised by the authorities of the Imperial Physical Institution in Charlottenburg, the favourite suburb of Berlin, against the introduction of electric traction on the local tramway lines, it is interesting to note the fate of the complaint which was made by the Senate of the University of Halle-a.-d.-Saale anent the proposed construction of an electric tramway along Ulrichstrasse, in that city, on the ground that the accurate working of the instruments in the physical department of the university would be interfered with. The Minister of Public Works has decided that the objection cannot be maintained, and, furthermore, that consideration cannot be given to the claim of the University Senate that the concession of the proprietors of another electrical line, which has been in operation for some time, be withdrawn, owing to alleged defects in the system of returning the current through the rails. It is said that the opinion of Prof. Slavi, of Königsberg, considerably influenced the decision of the Government official.

The Vibration Question in Germany.—Electrical engineers in the German capital are congratulating themselves upon the victory which the Berliner Elektrizitäts-werke has won on the vibration question. The "Viktoria" Insurance Company brought an action against its neighbour, the electrical company, to recover 362,000 marks (£18,100), being alleged damages sustained by the plaintiffs through their inability to let or sell their property on account of the noise created by the machinery of the defendants, which, it was averred, was felt to a considerable extent even in the topmost rooms of the building. The Landgericht viewed the case of the insurance company with but poor sympathy, and assessed the value of the injury sustained by it at only 25,000 marks (£1,250). Against this decision both parties appealed to the Kammergericht, with the result that the judgment of the lower Court has been quashed and the plaintiffs have been non-suited, the judges being of the opinion that the vibration complained of was not in excess of that which can be borne and which must be borne in a city like Berlin! And the Versicherungs-Aktiengesellschaft "Viktoria" is, like Lord Ullin, left lamenting.

Electric Traction in Belgium. — The Société Nationale des Chemins de Fer Vicinaux Belges has under consideration the substitution of electric traction for steam locomotives on several lines, that in the case of the Brussels and Petite-Espinette line having been made on October 1 last, since which time the 15-minutes' service has been perfectly regular. The E.M.F. necessary for working the line is furnished by the Union-Electricitäts-Gesellschaft, of Berlin, working the Thomson-Houston patent with which a contract has been made for 10 years, and which undertakes maintenance, repairs, and renewals, while assuming the whole responsibility. Wherever necessary, the trolley wire and feeders are protected by laths for preventing the contact of telegraph and telephone wires which might fall upon the line. Lightning conductors are placed at the generating station, on the line, and on the carriages, which latter are fitted with hand-brakes. In the event of accident, however, the current in the motors may be reversed, so as to effect an almost instantaneous stoppage. If, owing to an unfortunate coincidence, the hand-brake should happen to give out at the same time as the current, the train may be brought to a standstill, or allowed to descend a falling gradient, at very slow speed, by the two motors being put in parallel.

City and Guilds of London Institute. — The council of the institute have announced that the matriculation examination of the Central Technical Colleges will be held on September 17-20, and the entrance examination of the day department of the Finsbury Technical College on September 17. The new session in each college will commence on October 1. The diploma of "Associate of the City and Guilds of London Institute" has been conferred by the council of the institute upon the following matriculated students who have this year successfully completed the full course of instruction at the Central Technical College: civil and mechanical engineering—H. S. Andrewes, F. G. Arnould, J. E. Chapman, H. E. Fenwick, C. S. Hainworth, E. W. Hainworth, B. H. M. Hewett, E. W. Hummel, F. T. W. Lewis, F. E. Morgan, R. E Reeves, and H. Robinson; applied physics and electrical engineering—J. M. Barr, S. Beeton, C. Brandeis, W. M. Carver, A. D. Constable, S. Gilford, F. S. Grogan, A. C. Hanson, G. S. Hewett, C. D. Le Maistre, P. G. Phelps, W. Reilly, W. Roberts, H. G. Solomon, R. J. J. Swann, C. P. Taylor, E. L. Thorp, E. L. Webb, and N. J. Wilson; applied chemistry—W. G. Bennett, W. A. Davis, W. T. Gidden, C. Revis, E. M. Rich, and P. Spencer.

The Paris Exhibition Buildings.—The arrangements for the Paris Exhibition of 1900 are going briskly forward, and an estimate of the cost of the buildings, etc., arranged for has been received, which shows clearly the great extent of the undertaking. The total reaches $3\frac{3}{4}$ millions sterling, about double that of the last exhibition, which, it will be remembered, left a surplus. Two immense palaces are to be erected on the Champs Elysées, to cost £825,000. Then on the Esplanade des Invalides, the remaining buildings of the former exhibition are to be removed, with the exception of the immense machinery hall, and in their stead new buildings erected at a cost of just under a million. The exhibition is to extend right across the River Seine, and a broad bridge is to be erected, in addition to several footbridges, while the banks are to be levelled up, parts reclaimed, and the whole laid out as gardens, etc., at a cost of a quarter of a million.

Digitized by Google

Fountains, special pavilions, etc., will absorb £330,000, and these will include a separate exhibition of physical exercise and aerostation at the Bois de Vincennes. As many as possible of the mechanical exhibits are to be shown in motion, and the machinery for driving exhibits and lighting, etc., is to cost about a quarter of a million. Workmen's exhibits are to be admitted free, and £28,000 is laid aside for buildings, etc., while for such other purposes as musical performances, judging, etc., large sums are estimated. The sum named includes £24,000 for putting the site into a permanently satisfactory condition after the exhibition is over.

A New Application of Electromotors is described in *Dingler's Polytechnisches Journal* of July 26. The Martin furnace at the Lauchhammer Works, near Riesa, has to be fed eight times daily with about 13 tons of iron. This has hitherto been done by hand at great expense of time and money, apart from the considerable inconvenience suffered by the men from the fierce heat to which they were exposed. With the new feeding apparatus, one man, it is stated, can do in a tenth of the time the work of the four men who have hitherto been necessary, and is not subjected to anything like the same temperature. The old iron is now loaded in the yard into iron troughs, three or four of which rest on a small truck, which is hauled by an electric motor in front of the furnace. On a second parallel line is the feeding machine proper, a good sized truck, on which there are a large electromotor and three small ones. The feed wagon runs rapidly to one of the troughs; a long gripper swings out, catches it, lifts it from the truck, runs with it to the door of the furnace, thrusts it in, causes it to drop its contents, rapidly withdraws it, and lays it empty back in its place. The mechanism appears to be very simple, each movement of the apparatus being effected by a separate electromotor. The machine was constructed by the proprietors of the Lauchhammer Works themselves from drawings made in America, the electrical arrangements being furnished by the Aktiengesellschaft Elektrizitätswerke vorm. O. L. Kummer und Co., of Dresden. In order to accustom the men to the working of the new apparatus they were practised beforehand at a mock wooden furnace.

Light Railways and Cable Ways.—A lecture on light railways, cable ways, etc., has been delivered to the members of the Balloon Society by Mr. W. J. Brewer, C.E. Mr. Ernest Benedict took the chair. The chairman in his opening remarks said he was very much impressed by the railway constructed by Mr. Brewer at the Dyke, Brighton. He thought his system of overhead cable lines had overcome at least one difficulty which had been felt with regard to light railways. The lecturer, after referring to the importance to commerce of cheap and easy transit and to the conference which had been invited by the late Government on the subject of light railways, went on to describe the suspended cable-way system which he had invented and which had been successfully at work at the Dyke. The cost for a light railway of this kind would be about £250 per mile, exclusive of cars and engine. The advantages were—first, as to cost, which, taking weight for weight, would be vastly cheaper than a surface line of the ordinary type. It would not interfere with the land, and he believed it especially met the difficulty of transport now felt in many manufacturing districts, for by it goods could be speedily conveyed and at a cheap rate from the manufacturer to the railways. Then it did not require locomotives nor level crossings, nor in any way interfered with the ordinary traffic on roads. The system, he said, was capable of enormous development. There was no reason why whole trains of railway carriages, wagons, etc., should not be taken across rivers by this means, and he also proposed to ascend mountains by zig-zag lines. As to motive power, the system was equally open to gas or electricity. Mr. Brewer added that he had perfected a cable system for surface lines where an overhead track was not considered advisable. A resolution was moved by Mr. Lefevre, the president, to the effect that a system of light railways and cable ways would prove of great value to England and its colonies. This was seconded by Mr. S. Green, and carried after discussion.

New French Electrical Legislation. — The Chamber of Deputies has promulgated a new law regarding the laying or erecting of conductors of electrical energy other than telegraphic and telephonic lines, the salient points of which are as follow: Article 1 provides that, apart from public works, electric conductors which are not intended for the transmission of signals and of speech, and to which the law of December 27, 1851, is not applicable, may be laid or erected without authorisation or declaration. Article 2 provides that overhead conductors are not to be placed within a horizontal distance of 10 metres from each side of a telegraphic or telephonic line without the consent of the postal authorities. Article 3, that the Minister of Commerce, of Industry, and of Posts and Telegraphs, on the advice of the electrical committee, shall determine the modifications to be made in the lines at present existing within the above-mentioned prescribed distance. Article 4, that no conductor shall be fixed above or below public thoroughfares without an authorisation given by the prefect on the technical advice of the engineers of the postal and telegraphic authorities and conformably to the instructions of the Minister of Commerce, etc. Article 5, that the above-mentioned decrees do not apply to the installations of conductors of electric energy made for their requirements by the State departments or by the promoters of public works subject to State control; projects of these electric installations, as well as modifications therein, to be, save where they concern railways, etc., submitted for the approval of the Minister of Commerce. Article 6, that a permanent electrical committee is to be formed by the Minister of Commerce, half the members of which will be professional representatives of French electrical industries; this committee to give its opinion upon all questions that may be referred to it by the Minister; while Article 7 enacts that every electrical installation must be worked in such a manner as not to interfere by induction, or otherwise, with pre-existing telegraphic or telephonic lines; should, however, the installation absolutely require the shifting or modification of the pre-existing lines, the electrical committee will be consulted, and the cost of such shifting or modification must be borne by the promoters of the new installation. Due penalties are provided for contravention in any way of the new law, which was promulgated on June 25, 1895, and signed by the President, (M. Faure) and by M. André Lebon (the said Minister of Commerce, etc.).

Electric Traction in Germany.—For a long time past the question of the further improvement of the means of traffic in Berlin has been a standing subject in the deliberations of the Municipal Council. At the present moment, says the Berlin correspondent of the *Times*, this question arouses more interest in view of the industrial exhibition which is to be held next year at Treptow, which is a considerable distance from the centre of the capital and but poorly supplied with means of communication. There seems, however, little doubt that a concession will be granted for an electric tramway from the city to the exhibition. The question with regard to the facilitation of traffic within Berlin itself is more complicated. The capital

Digitized by Google

is provided with a metropolitan railway, a network of tramways, and also with omnibuses which, excellent as they confessedly are, have nevertheless not been found capable of coping with the increasing demands of the population. Aware of this, the civic authorities some time ago sent three of their members on a tour of inspection through large German and foreign towns in order to study the traffic arrangements and to compare them with those of Berlin. This task has been accomplished, and the mission has returned after visiting, among other cities, Dresden, Frankfort-on-the-Main, Strassburg, Paris, London, Liverpool, Glasgow, Edinburgh, Amsterdam, and Brussels. The verdict of the mission is that Berlin is in respect of traffic facilities, with the exception of electric tramways, as well supplied as any German or foreign town of large size, and that in many cases Berlin is far ahead. After hearing this report the committee appointed by the magistrates decided to recommend the municipal authorities to grant the funds requisite for carrying out experiments in Berlin with the most modern systems of electric tramways. Hitherto the Municipality has always contracted for the construction and administration of the tramway lines, but the committee has suggested that the authorities should now undertake the work themselves. Apart from the fact that the decision of the committee must be ratified by the Municipal Council, there are several obstacles in the way of a speedy realisation of this scheme. There still prevails, for instance, great diversity of opinion as to the comparative advantages of overhead and underground cables for conducting the electric current. The former will probably be employed for the less frequented streets and the latter for the great thoroughfares. Again, the concessions granted to existing tramway lines may prove a hindrance, as the companies, which pay large dividends, will probably be very tenacious of their rights. If, however, Berlin is to keep up its reputation as a model city in such respects, it must sooner or later introduce electric tramways.

Desecration Again.—Nelson's monument is now free, as we have previously stated, from so-called "desecration" by electric search-lights, but the Falls of Foyers now afford material for desecration discoverers. The subject was thrashed out a long time ago, but it is revived this week by the Duke of Westminster in his capacity of president of the National Trust for Places of Historic Interest and Natural Beauty. The duke writes: "Some months ago several questions in the House of Commons, and a considerable amount of comment in the Press, drew public attention to a proposal involving the destruction of the well-known Falls of Foyers on Loch Ness. As most people seem to have been left under the erroneous impression that the danger has been averted, I am desired by the National Trust to beg leave to inform your readers of the true state of the case. Workmen are at present employed at Foyers in making a tunnel from a point above the upper fall to a point below the lower fall. Through this tunnel the whole of the waters of the Foyers river will be conducted for the purpose of manufacturing aluminium by means of electricity, so that, as the agent of the Aluminium Company humorously states, 'the falls will not be injured, only there will be no water in them.' The proposed factory will not only destroy the finest waterfall in the United Kingdom, it will also emit hydrofluoric-acid gas, which will be most destructive to vegetation in the neighbourhood. In addition to this, it appears that the manufacture of aluminium will certainly create great spoil-banks, which the company are under no obligation to remove should they at any time suspend operations, nor, in the event of such a contingency arising, are they liable to restore the lakes of Stratherrick to their former levels, or to divert the water again to its original channel. Sir George Trevelyan, in reply to a question addressed to him last session in Parliament, stated that any investigation or restriction of this company's doings must be by the County Council of Inverness-shire. It is necessary to the operations of the company that certain roads should be diverted, and this cannot be done without the consent of the County Council, consequently that body commands the position. The National Trust has been given to understand that the Road Board of the County Council has reported in favour of allowing the diversions, but the Council has not yet ratified the decision of the Road Board, and has deferred all consideration of the matter until its October meeting. In the meantime Scotland will no doubt receive its annual quota of visitors, and it is very desirable that all who care for the beauties of the Highlands should join in a protest against the act of desecration which is in progress."

Electrical Conventions in Canada.—The fourteenth annual meeting of the American Street Railway Association will be held in Montreal on October 15, 1895, continuing for four days. The Victoria Rink, at the rear of the Windsor Hotel, has been secured for the exhibition of supplies and manufactures of every kind used in tramway operations. It is the intention of the promoters to make this exhibition "the most interesting of any yet seen," and a cordial invitation has been extended by the association to all manufacturers and producers of street-railway supplies to exhibit their machinery and wares. The Canadian Custom authorities have agreed to allow goods intended for the exhibition to cross the border at reduced rates. Exhibition space will be allotted on August 1, the charge for room being at the rate of 15 cents a square foot, not less than 50 square feet nor more than 1,000 square feet being rented to one exhibitor, unless by special arrangement. Electric power will be furnished to those who desire it at the rate of 45 cents per rated kilowatt of machine actually using current. The minimum charge will be 15 00dol. Mr. Stonewall Jackson, of 17, St. Sacrament-street, Montreal, is the local secretary for the meeting. It is interesting and amusing to note the comment of one New York journal, the *Electrical Age*, upon this exposition. It says: "Electricity's march is one of continual conquest, but so far it has not yet succeeded in breaking down the insulation of the frontier line between the United States and Canada. The American Street Railway Association will hold its convention this year in Montreal, but the bothersome Customs regulations confront intending exhibitors. According to the announcement of Secretary Partridge, the usual regulations will be somewhat relaxed on this occasion in order to afford the greatest facility for the entry and display of exhibits. The daily Press rant and preach about the annexation of Canada to the United States, but there the matter ends. Would it not be surprising, therefore, if the peaceful but all-conquering agent—electricity—accomplished the results so much desired by these vociferous newspapers? The National Electric Light Association held its convention in Montreal in 1891, and never was there seen in that country such a display of electrical apparatus and applications of the same; another convention, although of a different character, but essentially electric, to be held next October, will make our Canadian friends open their eyes and ask themselves why they are so near and yet so far from their great neighbour." The fact is, that many Canadians wish they were not so close to their "great neighbour." They know that it would be advantageous to them in many ways.

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 102.)

For the sake of improving our general understanding of curves we will revert occasionally to the use of oblique axes, but not for the treatment of any practical problem.

What line, for instance, is the line $x = y$, when the equation refers to such axes? Nothing will bring this so clearly before the mind as the following procedure. On a piece of drawing-paper plot the curve $x = y$, using rectangular axes, as in Fig. 6. On another sheet plot the line having the same equation, but using oblique axes, as in Fig. 7. Now trace this latter line on a piece of tracing-paper, drawing in only the line itself, the point O, and the axis O X, and place this tracing on the former line, so that the point O and the line O X of the tracing coincide with the same on the drawing. The same thing should be done with the points P, Q, R, S, T, K, M, N in Figs. 5 and 7; care being taken in each case to use the same scale on all four axes, O X and O Y and O X^1 and O Y^1.

In Fig. 6 we have three lines drawn which have one point common to all—the point O or (0, 0). Again, let it be remarked that the axes of reference O X and O Y must be imagined as extending to infinity, right and left, and up and down, and the equation $x = y$ means an infinite straight line, of which the line O D F is only a part. What have we to say of the line O A B C? What are these points: O is (0, 0); A is (1·45, 2·5); B is (2, 3·46); C is (2·9, 5);

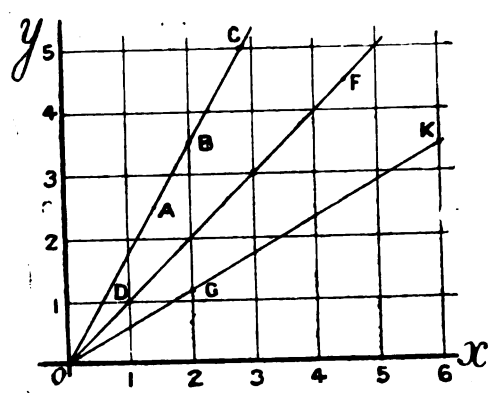

FIG. 6.

and we see there are points (1, 1·73), (3, 5·2), (1·73, 3), (2·3, 4) all on this line. If we tabulate them, the third column suggests itself at once.

x	y	$\frac{y}{x}$
0	0	anything
1	1·73	1·73
1·45	2·5	1·72
1·73	3	1·73
2	3·46	1·73
2·3	4	1·73
2·9	5	1·72
3	5·2	1·73

Here is a noticeable thing. The Y ordinates of all these seven points have a fixed relation to their X ordinates. Of course, when we are working on so small a scale we cannot be very accurate, and if the figures for $\frac{y}{x}$ be worked out to several places of decimals they will not appear to agree so well as in our table, which shows only two discrepancies—viz., points A and C. But then it must be remembered that we cannot measure values of x and y to more than one place of decimals at all accurately. Even the second is a guess, so that it is absurd to expect a quotient of two such approximations to be accurate to the second place, and they are unlikely, even in the first place, to give absolutely concordant results.

With the scale at our disposal, however, we may state that $x \times 1{\cdot}73 = y$, and put all discrepancies down to errors in reading. Take the points G and K and fill in other points on this line and tabulate them as in the above example, and we find for this line that $x = 1{\cdot}73\,y$. If it be now stated that the equation to either of these three lines may be written $a\,x = b\,y$, it must be at once evident that such a statement is true; for the line O F, a and b both = 1; for O C, $a = 1{\cdot}73$ and $b = 1$; for O K, $a = 1$ and $b = 1{\cdot}73$. Again, nothing brings this sort of thing so well home to the perception as actually drawing these lines and measuring them up. Draw also lines with various other slopes, but all passing through O. To most readers it is apparent that $\frac{y}{x}$ always gives a number equal to the tangent of the angle which the line makes with O X—*e.g.*, 1·73, or $\sqrt{3}$, is tan 60deg., and the angle C O X, is 60deg. as nearly as can be; also tan 45deg. is 1, and the angle F O X is 45deg.

We now have evidence sufficient for our purpose to enable us to state that for all straight lines passing through O the equation is $y = m\,x$, where $m = \frac{a}{b}$, the a and b being those of the equation $a\,x = b\,y$. Again, this is not a proof but "sufficient evidence for our purpose."

Let us now take our equation $y = m\,x$, and see if it suits any of the lines in Fig. 8. Take M Q P S. The values of the X and Y ordinates of the points on this line are indicated approximately on the diagram, but measured carefully come as follows: M = (− 1·58, 0) all distances to the left of O being considered negative as stated above, hence the X ordinate of point M is − 1·58; Q = (0, 0 9); P = (2 9, 2·55);

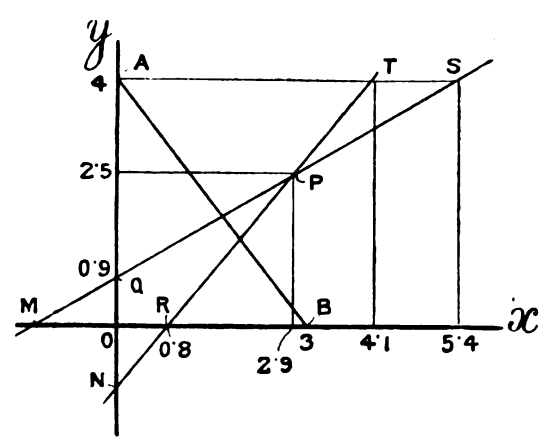

FIG. 8.

S = (5·45, 4). The very first point does not fit the equation, for if $y = 0$, $m\,x = 0$, and since we can see that here $x = -1{\cdot}58$, M must = 0; now we saw that m meant the tangent of the angle, and therefore if $m = 0$, the angle must be that whose tangent = 0; this is the angle 0deg., and a line at 0deg. with O X lies on O X. But M Q P S does not lie on O X, so the equation does not fit this line, and cannot therefore be used to represent it. By again having recourse to tabulation we may get a clue:

Point.	x	y
M	−1·58	0
Q	0	0·9
P	2·9	2·55
S	5·45	4

As a matter of fact, it is somewhat absurd to suppose that the general expression for a straight line could ever be arrived at without mathematics, and simple though the mathematics needed for this are, mathematics are in these articles forsworn, and we can therefore only beg the question. Let it then be pointed out that if m is to have a value other than 0 in the point M, we must add or subtract something to or from y, and if we did this at Q we could also make the equation fit. This point Q will perhaps help us; x is 0, and yet y has a value greater than 0; $m\,x$ is = 0 for any value of m when $x = 0$, so let us write $y = m\,x + 0{\cdot}9$; now we are safe at this point; $m\,x = 0$ and $y = 0\,9$, and obviously $0{\cdot}9 = 0 + 0\,9$. Let us see if subtracting this figure in the case of the point M gives a concordant result: $y = mx + 0{\cdot}9$, or $m\,x = y - 0{\cdot}9$; at this point M, $y = 0$, so $m\,x = 0 - 0{\cdot}9$, $m\,x = -0{\cdot}9$, $m = \frac{0{\cdot}9}{x} = \frac{-0{\cdot}9}{-1{\cdot}58} = 0{\cdot}569$; we see that

Digitized by Google

by using this value for m—viz., 0·569—and adding 0·9 to x we get a value for y which fits both these points M and Q; a little arithmetic shows that it fits the points P, S equally well. For this line then we write $mx+0{\cdot}9=y$. By an exactly similar process of reasoning and using the points N and R to help us as we did Q and M above, and on measuring carefully to find N is (0 – 0·971), R is (0·8, 0), P is (2·9, 2·55) as before, and T is (4·1, 4), we are able to arrive at the expression,

$$1{\cdot}214x - 0{\cdot}971 = y \text{ for the line N R P T.}$$

This is the same shape of expression as that for the straight line, M Q P S, and if we wish to state it, so that we can use it for any straight line on filling in the proper figures, we must use a letter for that quantity which has to be added or subtracted to or from mx; call it h, then we write $mx+h=y$, and if we draw any straight line on our sheet of paper and produce it to cut the axes of X and Y, these points of cutting will always enable us to find the correct values for m and h to make the equation fit the line. It must be evident by now that h is the value of y where the line cuts O Y. This in the three straight lines of Fig. 6 is O. In the case of the line A B (Fig. 8) h must then be 4; $mx+4=y$, and at the point B, $y=0$, and $x=3$, so $m=-\frac{4}{3}$; this negative value for m indicates that the angle A B X is greater than 90deg.

(To be continued.)

ALIOTH ALTERNATING-CURRENT DYNAMOS.

We illustrate herewith the alternating-current dynamos which have been made by Messrs. Alioth and Co., of Münchenstein, near Basle, in connection with the electric transmission plant which utilises the water power of the Reuse for the transmission of electrical energy to Neuchatel, a distance of 36 miles.

The general design of these alternators can be readily seen from Figs. 1, 2, and 3, which are appended. The bed-plate, which is box-shape, supports two pedestals, on which are placed self-oiling bearings.

After the coil is taken from the former it is insulated by many layers of paper and varnish before being placed over the projecting pole of the armature. This arrangement facilitates repairs—a coil can easily be withdrawn and a new one substituted in case of need.

The magnetic field in the centre of the armature is mounted on the main shaft, and has 18 or 12 poles according as the generator is designed for single-phase or three-phase currents. In the first case the 18 armature coils are grouped in two series of nine each. In this way the difference of potential between neighbouring bobbins is a minimum, and each of the two series are connected in parallel. In the second case, every third coil of the 18 bobbins are grouped in three sets. As each third bobbin

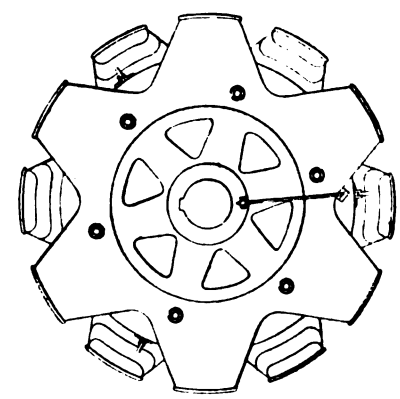

FIG. 1.—Magnet Stars for Three-Phase Work.

will in this arrangement be in the same phase, they are connected in series. Each of the three circuits are connected at one end, leaving thus three terminals furnishing three-phase currents. The alternator shown in Fig. 3 is designed for single-phase work, while Fig. 1 is the magnet star for three-phase work.

The whole of the poles of the one polarity are made in one casting of soft steel. The external faces of the pole-pieces are laminated with thin sheet iron let into the cast steel. The two star castings, one containing all the north poles and the other all the south, are strongly bolted together and mounted on a cast-steel centre, which is

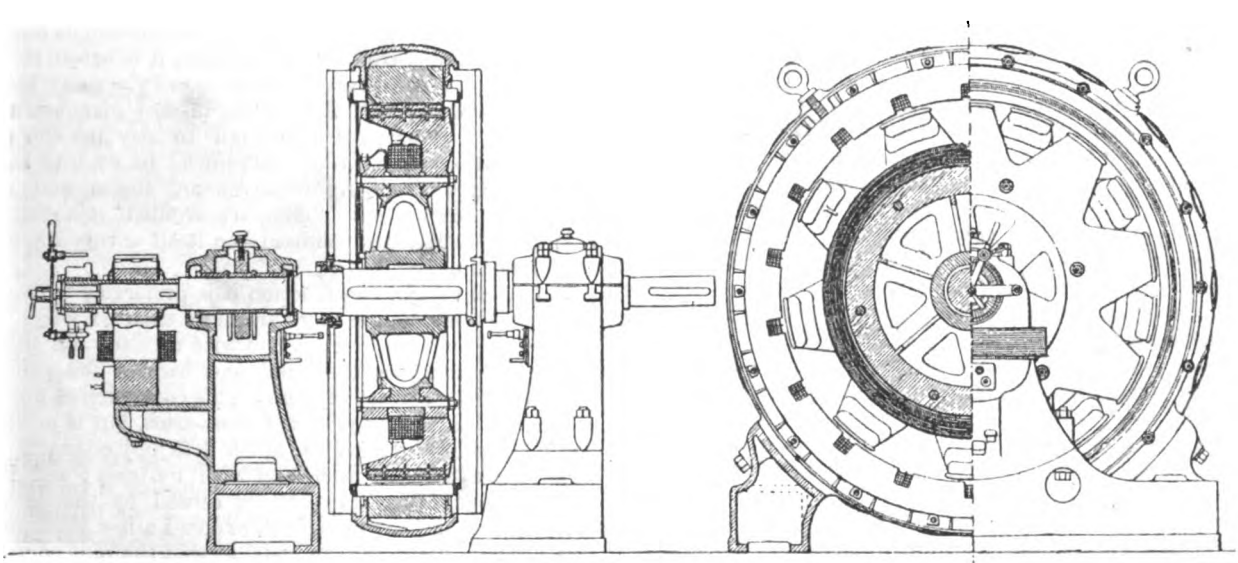

FIG. 2. FIG. 3.

The Alioth Alternator and Exciter Combined.

The bed-plate also supports in a plane perpendicular to the axis a protecting cylinder containing numerous openings for ventilation, and supporting the armature core. This has 18 polar projections radial to the axis and projecting towards the centre to carry the armature coils. The whole is of cast iron, except the iron core of the armature, which is made of laminated wrought-iron sheets, 16 mils thick, insulated from each other.

Each armature coil is wound on a wooden former of the correct shape, and consists of 60 turns of insulated copper wire, of a total length of 286ft. and of ·138in. diameter.

keyed to the shaft. In this way alternate north and south poles are obtained round the magnets.

On the periphery of the centre casting is placed the exciting coil. This is composed of 526 turns of insulated copper wire ·177in. diameter. The exciting current required is 20 amperes at 120 volts, and is supplied by brushes to collecting rings on the shaft. The exciting dynamo is mounted on the continuation of the shaft, as shown in Fig. 2, and is of such dimensions as to be able to excite two of the alternators at the same time. All the circuits are most carefully insulated from earth.

NOTES ON THE RECONSTRUCTION OF A SMALL CENTRAL-STATION PLANT.*

BY FRANKLIN L. POPE.

(Concluded from page 104.)

It has been found to be desirable to use a lamp of rather low efficiency for the street-lighting service, as there is always danger of leakage and short-circuits from wet boughs of trees and other objects getting into contact with the wires, and thus diverting an abnormal current through some portion of a lamp circuit. In such case, a lamp of high efficiency is pretty certain to be burned out, or at least to have its career of usefulness materially abridged. In this plant the average consumption of energy in the street lights, including lamps, lines, shunts, and leakage, is found to be about 140 watts per lamp of 32 c.p.

Perhaps the most ticklish part of the whole undertaking was the changing over of the Westinghouse system, which was a 1,050-volt primary and a 52-volt secondary, running at 16,500 alternations. In accordance with the new plan it was of course necessary to double the pressure both in the primary and secondary circuits, and to substitute 104-volt for 52-volt lamps throughout. A preliminary test of one of the transformers demonstrated that which perhaps might have been foreseen from theoretical considerations—viz., that a dangerous quantity of heat was developed within a few hours when it was used to convert from 2,000 volts down to 100. In order to utilise so far as possible the old transformers, and at the same time avoid the above difficulty, various expedients were resorted to. Wherever a group of consumers was located in one neighbourhood a pair of large transformers were installed, with secondary mains extending from 500ft. to 600ft. in various directions, these transformers being, of course, placed in series with each other. Scattered consumers, as far as practicable, were connected together in small groups, and supplied by a pair of small transformers coupled in the same way. The Westinghouse meters, having been originally constructed for a frequency of 16,500 alternations, ran slow when the frequency was reduced to 8,000. The necessary coefficient for correction of the readings was easily ascertained by experiment, and as fast as possible the meters were fitted with new discs, supplied by the Westinghouse Company at a trifling expense, and adapted to the lower frequency.

Of course, it will be understood that the reason for resorting to these various shifts and expedients was merely that we might utilise the old apparatus as far as it could possibly be done, and also that we might carry on the work of reconstruction for the most part with the ordinary working force of the establishment.

The horizontal double turbine, which is used to drive the two-phase generator, has done such good work that it deserves a few words of commendation. The selection of the best among the many available types of turbines for electric work is a matter which merits far more consideration from a scientific standpoint than it generally receives. Waterwheels, like dynamos and motors, are sometimes sold on commission by agents, and it not infrequently happens that the salesman who makes the largest "claims," especially if he sells his goods the cheapest, carries away the contract. It needs to be said, however, that there is a far greater difference than is often suspected in the amount of work different types of wheels will do with a given, and especially a limited, amount of water. There are, furthermore, a great many types of wheels in the market which, although as efficient as could be asked for with a full volume of water, are very far from being so when the volume of water is reduced even by a comparatively small percentage. It is but just to say that it is seldom that a turbine makes so favourable a showing, not only in this but in other respects, as the one provided by the company from which we lease our power. The following figures are selected from a much larger number obtained by actual measurement of its performance in the testing flume of the Holyoke Water Power Company.

Head acting on wheel, feet.	Revolutions per minute.	Quantity of water passing through wheel (cubic feet per second).	Horse-power.	Per cent. of efficiency.
16·66	156·25	81·75	124·50	80·99
16·80	155·00	70·79	109·37	81·18
17·02	154·50	63·42	95·86	78·39
17·26	156·75	52·19	73·42	71·95
17·44	152·25	42·55	53·71	63·90

These results are worthy of particular note, for the reason that they show a very high percentage of efficiency maintained through a wide range of variation in the quantity of water passing through the wheel—a most valuable characteristic for electric work. When the quantity of water used was diminished from 81·75 to 42·55 cubic feet per second, the percentage of efficiency fell only from 80·99 to 63·9, and, what is even more remarkable, it was found that the efficiency remained well above 80 per cent. over a range of variation of discharge from 83·22 to 70 cubic feet per second, or 15·9 per cent. More than one type of turbine which enjoys a high reputation and extensive sale among manufacturers will not reach 65 or even 60 per cent. efficiency at "three-quarter gate," while the 33-minute wheel above referred to has been found to give by actual test 78 per cent. under similar conditions.

The turbine carries upon its shaft a driving pulley 100in. in diameter, weighing 11,000lb., which serves as a balance wheel. It is also provided with a Replogle electric governor operated by three cells of gravity battery, which has never failed to do its work quickly and certainly, even under trying conditions.

In carrying out this work, some things have been learned by experience which may be of use to others called upon to advise or to undertake the construction of similar works, and I will therefore venture to summarise some of my conclusions as follows:

1. In considering the advisability of operating an electric plant by water power, do not on any account neglect to ascertain from authentic sources of information just how much water can be depended upon during the low stage in an extra dry year, for this is the measure of its value for electric work, except when used as an auxiliary to steam. The ordinary estimates of the commercial value of a water power are only too apt to prove preposterous exaggerations.

2. If rights-of-way or releases of damages can be obtained without too much trouble and expense, it is better to build the feeder line as directly across country as may be than to follow a highway. The saving in cost of construction will usually be more than enough to pay for the right-of-way, and on such a route there need be no interference from trees, while many inconvenient angles and much trouble in guying and bracing are avoided. Shorter and stouter poles may also be used—in itself a very important consideration.

3. In electric line construction it is preferable to dispense with cross-arms, unless there are more than six wires. The best arrangement is to place one wire on a top pin and the others alternately on the front and back of the pole, at a vertical distance apart of 12in. This construction not only costs less than properly-braced cross-arms, but is much less conspicuous and therefore much less objectionable in a public street; is less interfered with by trees; and is far more durable. Much trouble is caused by the decay of cross-arms after they have been exposed a few years to the weather; they split at the ends, so that the pins come out, and not infrequently break in the middle, thus fouling the wire.

4. In medium-sized towns and cities, especially in shaded streets, the incandescent lamp may be made to give a far better distribution of light for the same money than is possible with the "half-arcs" so extensively used, and is much less troublesome to maintain in good working order. My own experience leads me to think that the lamps ought not to be of less than 24 c.p. or more than 32 c.p. Use lamps of low rather than high efficiency, but run them at full candle-power, or even a trifle above. Good street lights, well arranged, and renewed sufficiently often, are the best possible advertisement for any electric company.

* Paper read before the American Institute of Electrical Engineers, Niagara Falls, June 27, 1895.

Digitized by Google

5. Use large transformers as far as practicable, placing the consumers within 500ft. or 600ft. radius upon secondary mains. We have used both two-wire and three-wire mains. The latter plan is certainly to be recommended when the distance approximates or exceeds 500ft., but for short distances—as, for example, when distributing within a single block at a pressure of 100 volts or more—it is a question whether the gain in cost of copper over the two-wire plant is of sufficient importance to offset the additional complexity.

6. It was found that raising the voltage in the residence district from 1,000 : 50 to 1,000 : 100 greatly improved the uniformity of distribution by lessening the potential drop without entailing any corresponding disadvantages. It would seem to be preferable on every account to use the higher pressure.

7. One of the most important minor points in the management of a plant is apt to be too much neglected—the maintenance of the insulation of the wires by promptly replacing all cracked and broken insulators, and by keeping the wires absolutely free from contact with uninsulated objects. The covered wires which lead into the hoods of the street lamps need to be carefully looked after.

8. Number all the poles with yellow paint applied with a stencil on a black ground; and keep a record book of the position of each one and its distance by the line from the test station.

9. In selecting a turbine wheel, consult competent authorities as to the available fall and minimum quantity of water, and when making the purchase do not expect to get a 1,000dol. wheel for 100dol. Pay a fair price, and insist not only that the wheel shall be well made in every way, but that it shall be tested by an expert before acceptance. If it does not give an average efficiency of 76 per cent. between half gate and full gate, it is not advisable to accept it, inasmuch as you can easily do better, as our own experience proves.

10. I think our experience shows that it is possible to largely increase the net earnings of an old plant without necessarily refitting it throughout, but plenty of time should be taken for consideration as well as for execution in order to secure satisfactory results with a moderate expenditure.

THE QUALITIES OF MANGIN AND PARABOLIC MIRRORS.

We have received the following communication from Herr F. Nerz on the above subject:

A reply was published in the *Electrical Engineer* of July 5, by M. J. Rey, chief engineer to Messrs. Sautter, Harlé, and Co., Paris, to my communication in the same paper of June 14.

The last statement of M. Rey calls for some corrections.

It is true that I was not allowed, as an expert of the Elektrizitäts-Aktiengesellschaft vormals Schuckert und Co., of Nuremberg, to attend the comparative trials carried out at Toulon, although the French firm Messrs. Sautter, Harlé, and Co. were allowed to be represented as they liked. My firm, in spite of this, trusting to the honour and impartiality of the French Marine Commission, allowed their projectors to be available. In handling these, only persons of French nationality were employed, who were instructed by me before the trials in Toulon, and during the period of the same in the use of projectors, as they were not versed in the technicalities of projectors. It is self-evident that by this dissimilar representation of the competing firms, the French firm obtained a favourable position. Long before the trials, in reply to a question of Messrs. Schuckert and Co., the French marine authorities fixed the current to be chosen for the projectors, and consequently our representative acted correctly in, as requested, not furnishing a current of greater intensity than 100 amperes for the mirror of 38cm. That this was not due to fear that the mirror could not withstand the heat is contradicted by the fact that Messrs. Schuckert recommended up to 120 amperes for 38cm. mirrors in cases where diffusers were to be employed, and apparatus of this kind have been delivered in numerous instances.

M. Rey is in error when he maintains that I adduced as the chief advantage of the parabolic mirror that it had a short focal length. In my paper "Scheinwerfer und deren Verwendung" I expressly stated: "The greatest advantage of the parabolic mirror, as compared with the Mangin mirror, is that its construction adapts itself to the demands of theory. All that is required is to choose for a given diameter of mirror the correct focal length, so as to secure the greatest possible performance."

In the same place I have indicated how the proper proportion between the diameter of the mirror and the focal length is to be obtained. That Messrs. Schuckert and Co. at the present time make mirrors of 90cm. diameter and 31cm. focal length, can be found by M. Rey in the projector tables published by me. The grounds why in one case larger and in another case smaller focal lengths are to be chosen may be obtained from my previous publications and those of my firm. Should, however, a reader put the question why Messrs. Sautter, Harlé, and Co. in their mirrors always aimed at reducing the focal length, M. Rey would have to give a reply which would differ little from my statements.

With respect to M. Rey's enquiry as to the degree of accuracy in parabolic mirrors, I can reply that the actual focul lengths of the separate mirror zones differ from those aimed at only by amounts lying in a circle of 1mm. radius. In connection herewith, I must state that the focul lengths aimed at do not unite at one common point, but that according to the different diffusion of the separate zones of the parabolic mirror, the focul lengths of the same are shifted on the axis of the mirror. By this arrangement it is possible to correct the unequal illumination of the rays of light produced by a mathematically accurate parabolic mirror within fixed boundaries—that is to say, to raise the homogeneity of the rays of light as required, as I have already shown in my previous communications in correction of Messrs. Sautter-Harlé's fifth paragraph.

As regards the conditions laid down for the delivery of glass parabolic mirrors for a Government, M. Rey is correctly informed with regard to the figure of 7mm. This figure, however, does not refer to a sphere within which the rays from an infinite distance unite, but to the section of the axis in which this is cut by the various reflected rays. With rays which according to conditions of delivery are thrown back with very small axis angles, a removal of the cutting point by + or − 3·5, in all 7mm., results in a very small deviation.

This circumstance neither M. Rey's guarantor nor M. Rey himself has forgotten to take into consideration. Far from me be it to make M. Rey an adherent to the parabolic mirror, and therefore I desist from going more closely into the separate points of his last communication. Time, which has converted M. Rey or his firm from enmity to the horizontal lamp to friendship for the same, will also shortly bring about conversion to the parabolic mirror.

But with respect to the Toulon trials, I must return to this subject. M. Rey maintains that I have been falsely informed by my company's agents, and that the experiments were not favourable to the parabolic mirror. This I contradict, and in support adduce decisions the competency of which cannot be denied by M. Rey: (1) the competent French authority speaks explicitly of the superiority of our glass parabolic mirror—if this superiority had not been considered great enough to introduce the glass parabolic mirror into France in place of the Mangin mirror, then certainly no reference would have been made to the superiority if this had not been proved; (2) M. Rey himself has in Toulon admitted to me, in the presence of witnesses, the superiority of our glass parabolic mirrors.

The Toulon trials have shown that a 65-ampere parabolic mirror gave the same results as an 82-ampere Mangin mirror, and demonstrate only the correctness of the results which had been obtained elsewhere, which showed the superiority of the parabolic mirror.

A New Telegraph Line.—The Government of India have approved of the construction of 162 miles of telegraph line from Hoti Mardan to Chitral.

NOTES ON HYDRAULIC POWER SUPPLY IN TOWNS—GLASGOW, MANCHESTER, BUENOS AYRES, ETC.*

BY EDWARD B. ELLINGTON.

The distribution of hydraulic power in towns has not previously been brought directly before the members of this institution, and the fact that works of this character have just been completed in Glasgow renders the present meeting a suitable opportunity for dealing with an engineering subject of such continually increasing importance.

Existing Hydraulic Power Works.—The present position of the various undertakings which have been established for this purpose is summarised in the accompanying Table I.

TABLE I.—Existing Hydraulic Power Works.

Place.	Year of establishment.	Length of mains.	Largest diameter of mains.	Engine horse-power.	Delivery of water per week.	Number of machines worked.	Pressure per square inch in mains.
		Miles.	Inches.	I.H.P.	Gallons.	No.	Lb.
Hull	1877	2½	6	250	100,000 to 500,000	58	700
London	1884	76	7	3,400	9,500,000	2,300	750
Liverpool	1888	18	6	800	1,000,000	453	800
Melbourne	1889	18	6	800	1,500,000	413	750
Birmingham	1891	3½	6	52	78,000	—	700
Sydney	1891	12	6	688	740,000	200	750
Antwerp	1894	4½	12	1,000	3,300,000	Turbines at three stations	750
Manchester	1894	12	6	800	1,000,000	247	1,120
Glasgow	1895	9	7	600	Nil	Nil	1,120

General Arrangement.—Of the hydraulic power works in London full particulars have already been given to the Institution of Civil Engineers, and as all such works have much in common it is hardly necessary to add any detailed account of the most recent establishments in Glasgow and Manchester. The supplies in these towns differ from those given elsewhere in the higher pressure employed—namely, 1,120lb. per square inch. This pressure was adopted in Manchester on the recommendation of the author and his colleague, Mr. Corbet Woodall, in order to render the power available under the most economical conditions for working the numerous hydraulic packing presses within the area of supply in that city. The works in Manchester have throughout been carried out under the supervision of Mr. Woodall, acting for the Corporation. In Glasgow also there is a considerable demand for power for pressing; and Mr. Gale, who is here responsible for the general scheme, considered it advisable to be able to supply the same higher pressure. The plans and specifications for these works were prepared by the author's firm as consulting engineers, and their execution has been under the control of the water department of the Corporation, and especially of Mr. Cochrane, Mr. Gale's assistant mechanical engineer. The general arrangement of the works in Glasgow and Manchester was shown by diagrams. The engine-house in each city is laid out to contain six sets of vertical triple-expansion engines of 200 i.h.p. each, of the kind introduced by the author in 1880, but in the earlier engines the cylinders were arranged compound with one high-pressure and two low-pressure cylinders. The scale on which the two stations have been planned is the result of the experience gained in London, which has demonstrated that for hydraulic power supply a station of about 1,200 h.p. is the most economical both in working expenses and in outlay of capital.

Engines.—The principal dimensions of the pumping engines in Glasgow are as follows: high-pressure cylinder 15in. diameter, intermediate 22in., low-pressure 36in., and all three 24in. stroke; cranks set at 120deg. in the sequence—high, low, intermediate; pumps, single acting, 13in. diameter and 16in. stroke; surface condenser, 530 square feet of condensing surface; crankshaft journals, 7in. diameter; flywheel, 7ft. diameter, weighing two tons. The engines are designed to work with a steam pressure of 150lb. per square inch above atmosphere, and this is the boiler pressure adopted in the recent stations in London and Glasgow; but in Manchester the pressure of only 120lb. is used, at the request of the committee of the Corporation who had charge of the undertaking. The Glasgow engines have not yet been tested for economy, but the London station of similar character at Wapping gave a consumption of 14·1lb. of water per indicated horse-power per hour (*Proceedings*, 1894, pages 536-51).

Boilers.—The boilers in Manchester are of the usual Lancashire pattern, five in number, 7ft. 6in. diameter and 30ft. long. In Glasgow, as coke breeze is to be used for fuel, and as there is ample space under the reserve water-tanks, it was determined to arrange the house for eight Lancashire boilers, 7ft. diameter and 30ft. long; at present only four have been fitted for the three sets of engines already in place. Since the station was designed, the Corporation have determined to add to the boilers Watmun automatic circulating apparatus for increasing their efficiency. Both in Manchester and in Glasgow two of Green's economisers, with 160 tubes each, have been fitted at the back of the boilers. In the recent Wapping and City-road stations in London, Fairbairn-Beeley boilers have been used, and these with the economisers have given under trial the remarkable result of 11·11lb. of water evaporated from the temperature 63·5deg. of the hot-well feed, and at the temperature of 362deg. corresponding with 143·3lb. pressure above atmosphere, or 13·44lb. of water evaporated from and at 212deg. with 1lb. of dry Nixon's coal, having a calorific value of 15·5lb.; the thermal efficiency of the boiler was therefore 86·7 per cent. It will be interesting to compare this result with that of the Glasgow boilers when they can be tried.

Accumulators.—The accumulators at the Manchester and Glasgow stations are of the same capacity—namely, two at each station, having rams 18in. diameter and 23ft. stroke, and each loaded with 127 tons inclusive of ram and casing.

Delivery.—Each set of engines is designed to deliver 230 gallons per minute at a speed of 60 revolutions, or 240ft. of piston; but it is not intended that they should be run in regular work at more than 50 revolutions, or 200ft. per minute. Assuming that five engines are working at the same time, the total regular working capacity of the stations when fully equipped is 57,500 gallons per hour at 1,120lb. per square inch. The maximum recorded during regular work in an hour at the Wapping station of the London Hydraulic Power Company with five engines running has been 66,000 gallons at 800lb. per square inch, or an average for each of the five engines of 45 revolutions per minute. The reason for dividing the power at a station into so many units is of course that the demand for power, as for lighting, is so irregular that the maximum demand is maintained approximately for only an hour or two during any day.

Site of Station.—The general arrangement of the Manchester and Glasgow stations has been determined mainly by the configuration and situation of the site selected. At first view the proposed site for the Glasgow works appeared difficult to lay out satisfactorily; but the solution ultimately arrived at, the author thinks, has fulfilled the

* Paper read at the meeting of the Institution of Mechanical Engineers at Glasgow.

Digitized by Google

required conditions in a fairly satisfactory manner, both mechanically and architecturally. The problem was solved by dividing the site into two areas at different levels by a heavy retaining wall, and an attempt has been made to give the buildings a more imposing character than has been usual in such works. The position of the site seemed to require this, and the suggested elevation was at once accepted by the committee as being appropriate to its surroundings.

Water.—Both in Manchester and in Glasgow the water supply is taken from the corporation mains: so that no pumping is required to fill the tanks, and no filtering apparatus is needed. The whole arrangement of these stations is thereby much simplified as compared with those in London, where Thames or canal water is used; it is also unnecessary to have the same large reserve of water in the tanks. At the Wapping station in London, for instance, the tanks over the boilers have a total capacity of 237,000 gallons, and in addition there are underground reservoirs of filtered water containing 500,000 gallons. In Manchester and in Glasgow the whole storage provided is only 230,000 gallons and 200,000 gallons respectively. The pipes in the engine and boiler houses are all arranged on the duplicate or circuit system, and great attention has been given to the provision of sufficient access to all parts of the machinery.

Mains.—The supply from the stations in Manchester and Glasgow is taken to the streets through four mains, which are laid in circuit, with valves at intervals of about 440 yards. Connecting mains have a valve at each end, so that the majority of buildings supplied have two ways by which the power can be obtained. The largest mains laid in Manchester are 6in. internal diameter, and in Glasgow 7in. The reason for the adoption of 7in. mains in Glasgow is that there is a tendency to reduction of bore through corrosion due to the action of the Glasgow water; in consequence of which Mr. Gale wished the mains to be larger than the usual size.

Joints.—The joints of the pipes are precisely the same as those used for the lower pressures in London and elsewhere. The packings are guttapercha rings inserted in a V groove, and the pipe ends are spigot and faucet. The setting back of the flanges, so as to leave a considerable projection of the pipe ends beyond them, has greatly strengthened the pipes, without adding any weight; and so far as is known, only one failure of a pipe flange made on the author's plan has occurred during the last 10 years. This failure occurred through a settlement in Bishopsgate-street, London. With pipes made without the flanges set back, many failures have occurred.

Registration of Supply. — Always supposing that the demand for the power is large enough, the commercial success of public hydraulic power stations is largely dependent upon the proportion of the total output which can be accounted for by the meters employed. It is impossible to maintain a high efficiency of the machinery in use without a great deal of time and attention being given to the registration of the supply. The means employed for registration, therefore, and for the maintenance of efficiency, are of great interest and importance in connection with the distribution of hydraulic power. This particular question has not been previously dealt with by the author so fully as to render it superfluous to revert to it here. The London supply of power is so largely in excess of anything required elsewhere that the experience gained in London is the most valuable, and the present remarks on this head will apply mainly to London.

Efficiency.—The first two matters to determine are the quantity of power delivered by the engines into the mains, and the rate of flow as far as possible throughout the day. The quantity of power is ascertained by a record of the engine revolutions obtained with the usual counters. A constant is used, which for the London engines is reckoned as 4·8 gallons per revolution. This constant has been verified from time to time by observing the quantity delivered from the tanks during some hours by direct measurement, and no alteration is allowed in this constant under any circumstances. The counter readings are taken in London at six o'clock in the morning and six o'clock at night, and are entered in the engine-room log-book. These readings give the amounts from each station every 12 hours, and the returns from the several stations are collected and entered in a general log-book. Every six or seven weeks the meters are read on the consumers' premises, and the totals are collected, and the efficiency of the system is determined by the fraction representing the ratio of the quantity registered by the meters to the quantity pumped as determined by the counters. This ratio in London is found to vary considerably in different quarters of the year, and in different years. It has never been higher in any quarter than 0·9826, and has never been lower than 0·8560. The following are the ratios of efficiency for the 10 years 1885 to 1894 in London, and for six years in Liverpool:

	London.	Liverpool.
1885	0·8665	—
1886	0·9250	—
1887	0 9400	—
1888	0·9370	—
1889	0·9545	0·945
1890	0·9576	0·959
1891	0·9089	0·9853
1892	0·9240	0·9304
1893	0·9119	0·9543
1894	0·9181	0·9592
Average	0 9243	0·9555

The causes which produce the variations in these ratios of efficiency are themselves very variable, and with an extensive supply, such as obtains in London, it would be almost impossible to identify the locality of the losses if the record of daily deliveries and the quarterly reading of meters were all there was to depend on. The sources of waste and error are of two kinds: firstly, those which occur before the supply reaches the consumers; and secondly, those which appertain to the consumers' machinery and to the meters. The losses of the first kind are made up of leakage past the suction-valves of the pumps; of leakage in the mains, and in the packings of the valve glands connected with the mains; and of losses in frosty weather by pumping water to waste for the purpose of maintaining the circulation. The losses of the second kind are due to defects in the registration by the meters; to leakage from consumers' machines, where, as is generally the case, the exhaust water only is registered; and to drainage from consumers' machines and pipes. The last loss is considerable in winter, when consumers make a practice of draining their pipes after work every day.

Automatic Flow-Recorders. — In order to maintain a sufficient control over all these sources of waste, it is of the first importance to know the minimum flow through the mains at times when it may be supposed that no work is being done. To ascertain this, automatic recorders are fitted at all the pumping stations. One of these consists of a drum, actuated by a clock, and carrying a paper strip, which is divided into quarters of an hour and hours by pins fixed on the drum; and over the drum are a series of armatures carrying pins, which prick a hole in the paper as each engine completes 100 revolutions. The descent of the armature is determined by electric contact, and one armature is electrically connected with each engine. The clocks at the different stations are synchronised, and the paper tapes are cut off daily, and the maximum and minimum deliveries during an hour are registered daily. The maximum delivery is chiefly used for determining load-factors, and the amount of power required for supplying a given number of machines; while the minimum daily registration is of the greatest value in determining the condition of the whole system, including the consumers' own machinery. The minimum flow varies greatly from day to day, but it never falls below a certain amount. This mode of registration was introduced by the author in 1888, and it has been found that the minimum flow rises pretty regularly as the supply is augmented. The following are the maximum and minimum registrations in London for the June quarters from 1888. It will be observed that the minimum flow has increased at a greater rate than the maximum, and that the maximum has followed fairly closely the increase in output. The latter fact is more clearly brought out by the comparison also given for the same years of the load-factor—that is, the ratio of the average flow per hour to the maximum flow.

Digitized by Google

Year.	Total water pumped in June quarter. Galls.	Max. flow per hour. Galls.	Min. flow per hour. Galls.	Annual load factor.
1888	29,238,000	39,120	1,200	0·286
1889	39,873,000	49,920	1,776	0·328
1890	48,172,000	61,248	1,604	0·306
1891	65,386,000	79,330	3,360	0·339
1892	77,103,000	91,920	3,984	0·326
1893	82,586,000	101,760	4,500	0·323
1894	96,876,000	114,096	4,800	0·338

The causes which have led to the comparative increase in the minimum flow since 1890 have been extremely difficult to ascertain. Since 1890 a great deal more hydraulic power has been used at the stations themselves, because most of the water from the river has since then been pumped into the unfiltered-water reservoirs by means of hydraulic pumps; but as the hydraulic power so employed is registered, this should not have affected the ratios of efficiency, which have been lower for the years 1891-94 than in 1887-90. Recently, arrangements have been made to stop for one hour on Sunday morning all use of hydraulic power at the stations, and during the current year the minimum flow has fallen to 4,080 gallons in the hour, with a delivery of 112,000,000 gallons in a quarter, and a maximum flow of 144,000 gallons per hour. These figures show as good a result as in any previous year. From such facts as these, and for other reasons, it appears probable that the principal cause of the difference is to be found in the meters and in the consumers' machinery.

Detection of Waste.—The whole of the 76 miles of mains in London are as a rule in communication with one another; but certain valves are kept closed in such a way that the several main circuits are in communication with one another at the central station only. The superintendent at the central station has it then in his power at any time to divide the supply into four distinct sections, and by observation of the pressure gauges it can readily be ascertained through which section an abnormal flow is occurring. The main in which this abnormal flow is proceeding has then to be shut down at intervals, till at last the leak is run to earth. Great care and experience are required to determine the exact spot, as the water seldom appears through the surface of the street, and usually the only indication is the noise it makes in passing through a valve very slightly opened, which is detected through a metal rod pressed against the valve and held to the ear. Irrespective of any special indication afforded by the minimum readings, the whole of the mains are being constantly tested in this manner; but it is a work of considerable difficulty, because the supply has to be maintained as required throughout the night, and it is only during two or three hours in the early morning that anything of the kind can be done, and even then special arrangements have to be made with the consumers. The principal difficulty arises from the very small flows that have to be detected; for instance, the quantity of power water pumped into the mains and unregistered during the last quarter of 1894 was 6,900,000 gallons out of a total of 111,000,000 gallons, or 6·22 per cent.; but this 6,900,000 gallons to be accounted for by testing the mains is the result of water flowing continuously at the rate of, say, 3,000 gallons per hour, which is thus only about 2 per cent. of the maximum rate. The whole of this flow is distributed throughout 76 miles of mains, and over 2,200 machines with all their pipes and accessories. At the pressure of 750lb. per square inch 3,000 gallons per hour would pass through an orifice of only $\frac{5}{16}$in. diameter, which shows how small in reality the leakage from the mains must be. The principal source of waste is undoubtedly on the consumers' premises. It has been found necessary to inspect regularly all consumers' machinery in order to prevent waste from leaky valves and glands. Every machine from which the exhaust is measured is thus inspected every quarter, and the owners are called upon to make good defects. Many of the meters in use cannot be depended upon to register small flows, and a good deal of waste passing leaky valves thus fails to get registered; but some of the waste occurring in this way does evidently get registered, because it is almost invariably found that the quantity unregistered is less than would be represented by the minimum flow. Thus in the figures just given for the last quarter of 1894 about 30 per cent. of the minimum flow was registered. A further cause of loss has already been mentioned—namely, the drainage of pipes and cylinders on consumers' premises. This no doubt is the cause of the registrations being better in the summer quarters than in the winter. In severe frosts the drainage of the pipes and cylinders is an important matter, and it has been found advisable to facilitate the practice. There are other losses due to washing out and testing the mains, etc.; water used for testing extensions of mains is allowed for in the registered quantity. On the whole, therefore, it is no doubt a good result to have succeeded in registering an average of 93 per cent. of the quantity pumped during the nine years 1886-94.

Frost.—The severe and prolonged frost of last winter did not seriously affect the supply. About 1,150,000 gallons was pumped to waste during Sundays in order to maintain the circulation; but after allowing for this 91·65 per cent. of the total water pumped was registered. This fact alone is conclusive; but in a few places sub-mains in exposed positions were frozen, though in nearly every case they were quickly cleared. No consumer, it is believed, was seriously inconvenienced. The frost was down in the ground quite 3ft. in places, and there were five or six instances of broken mains. The damage done was greater than on any previous occasion. The surface of the roads was so hard that the water could not get through the paving, and in two or three places found its way into cellars. In two instances the water was forced between the concrete and the wood paving, floating the latter, and at last finding a vent about 100 yards away from the break. It was not found necessary to relay the pavement thus lifted, except in a few places, for it settled down all right again after the water had run off. There were other novel experiences of the severity of the weather. In the Thames Embankment subways there were several degrees of frost, and during its continuance, in order to reduce the risk, the area of supply was divided into sections, and the embankment main had thus a dead end; the temperature fell, the main contracted, a large number of the joints opened, and huge icicles formed round the flanges. As soon as this was discovered, the valve shutting off the City was opened, the water which is sent into the mains at 60deg. flowed through and thawed the pipes that had contracted, and most of the joints again became quite sound. In connection with this question of warming the water, it is interesting to note that the water pumped from the river was below freezing point. The water is heated by passing it through the surface condensers of the engines; but at the new stations where the triple-expansion engines are used, it was found that the temperature could not be raised much above 40deg. in the filtered-water tanks, and in order to maintain the water at the higher temperature of 60deg. it was necessary to destroy the vacuum in the condenser, thereby rendering the engine less economical for the time being. Another experience may be mentioned in connection with low temperatures which shows that high apparent economy is not always real economy. At the Wapping and City-road stations the economisers are arranged much in the same way as for the Glasgow works. The temperature of the gases leaving the economisers was reduced to 238deg. or 240deg., and the temperature of the hot-well condensed water entering the economiser was 65deg. or 70deg. The consequence has been that it has been found necessary to renew the economiser tubes after three years' work, owing to the condensation on the outside of the tubes and their consequent corrosion. The cost of the renewal is larger than the saving of fuel effected. Arrangements are now being made to obtain a higher hot-well temperature.

Meters.—At first sight it would appear desirable to use high-pressure meters. Where these are used, the conditions of supply are much simplified, because the condition and arrangements of the consumers' machinery are then of no direct consequence to the works supplying the power, since all water taken from the mains for any purpose is measured, and this is undoubtedly the ideal arrangement. There are, however, difficulties in the way. The high-pressure meters to stand 750lb. to 1,200lb. per square inch are necessarily costly. For hydraulic purposes it is essential, in the author's opinion, that they should be positive meters. A positive

Digitized by Google

meter has three disadvantages: it will never for a long period register a small flow; it offers considerable resistance to the flow at high velocities; and if it gets out of order it may stop the flow almost entirely. Now, a stoppage of supply from any cause is more serious than a temporary failure to register; and the balance of advantages is found to be ultimately in favour of the low-pressure meters registering the exhaust from a tank into which the exhaust-pipe discharges. The kind of meter adopted by the author is the Parkinson, which is closely similar to a gas-meter. If it stops working the tank overflows, and the nuisance causes a report to be sent in at once. It will register every drop of water, provided the water is clean and the meter properly set. On the other hand, it takes up a good deal of room, and if dirt or rubbish is allowed to pass into the drum its accuracy is soon affected. A good deal of trouble is experienced from this cause. Where bad oil and packing are in use, or the glands and rams are in a bad condition, these meters have frequently to be changed two or three times in a single quarter, while in other places, where the machinery is better attended to, they will work for two years or more. With the Kent positive low-pressure meters, which are largely used in London, there is not the same difficulty, and in many places these are preferred, because the space taken up is so small that there is no noise from the falling water. But they do not register accurately a small flow. On the whole they are well adapted for high pressure, and in several places it is only on the high-pressure side that the power can be registered, as, for instance, at the London Docks, where only a portion of the supply is taken from the hydraulic power mains, the remainder being supplied from the dock pumping stations. The principal difficulty with high-pressure meters is in connection with the counter. The spindle must be light, in order to avoid loss of pressure, and the stuffing-box must be kept tight under the wear. After passing 1,000,000 gallons they have been found under test still accurate within 1 per cent.

Application of Power.—Hydraulic power has to be supplied under competition with steam, gas, and electricity, and the success which has attended its introduction shows conclusively that it is well able to meet this competition for lifting and for other intermittent work. None of the supply systems which have been established have aimed at meeting the demand for continuously running motors, except in Antwerp, where the supply has been laid out as a means for generating electricity for lighting. At first sight it is somewhat difficult to see how this can be an economical mode of employment. There are, however, a few places in London where the hydraulic power is used to generate electric current. The apparatus consists of a Pelton wheel, with the armatures of the dynamo mounted on the same shaft. The following are the particulars of a trial made with this apparatus at the hydraulic engineering works at Chester in October, 1894: Pelton wheel, 18in. diameter, 54 buckets; Elwell-Parker shunt-wound dynamo for charging accumulators, having a commercial efficiency of 87 per cent. as tested by the makers; speed, 1,671 revolutions per minute; bore of nozzle, 0·175in.; hydraulic pressure, 725lb. per square inch; output, 37½ amperes at 120 volts; water consumption, 20 gallons per minute; power in water 10·15 h.p., in output 5·99 h.p.; efficiency, 59 per cent. This is not the highest efficiency that could be obtained, for the wheel and dynamo were not perfectly adapted to each other. External resistance had to be used for keeping down the voltage, and at this output the dynamo was somewhat overworked. In a previous trial, with 0·16in. nozzle and an output of 26 amperes at 122 volts, the efficiency was 59·86 per cent. It is unlikely, however, that even under more favourable conditions the conversion can be effected with a greater efficiency than 66 per cent.

(To be continued.)

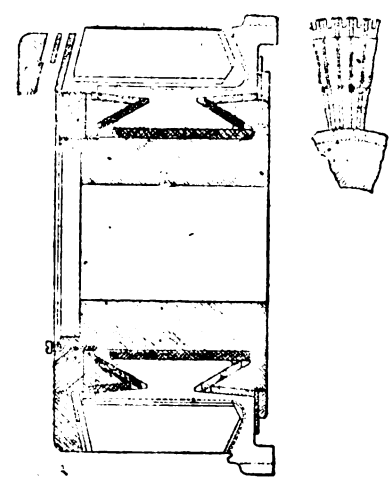
Electric Railways in Germany.—According to the *Berliner Tageblatt*, the directorate of the Lübeck-Büchen Railway purposes introducing electric traction on the line between Hamburg and Lübeck; and the State railway authorities intend, it is said, to electrically haul the trains running between Hamburg and Harburg.

COMMUTATOR WITH MOVABLE SEGMENTS.

Any arrangement whose object is to relieve the owner of a dynamo or the manager of a central station from care or responsibility is worthy of attention. A description, therefore, of the Painter-Morrison movable-segment commutator will be interesting. This commutator differs from the type at present in use in that where renewal is essential it is not necessary to disengage the armature wires from their segments. This operation, it is well known, is frequently as tedious as it is troublesome; it is more or less injurious to the wire; and it occupies considerable time, during which the dynamo is useless. The new arrangement, while obviating these difficulties, also results in economy being attained by permitting the utilisation of all the material save about a tenth of the thickness of the segments.

Figs. 1 and 2 show, in cross-section, the method of construction. As will be seen, the central bushing is fixed and maintained in position in the same manner with existing types, the only difference being that the contact surface is plane from one end to the other. Each segment is, on two sides, shaped into a double bevel, which engages in two V grooves. In order to renew the commutator it is not necessary to withdraw the tube or bushing from the shaft, nor to detach the wires.

The segments are all of the same size. They can be joined beforehand in the form of a ring held by a hoop and slid altogether on the bushing, as shown in Fig. 2, or mounted separately on it. The fixing shield is afterwards screwed on, which simultaneously fastens all the segments. It is seen that in this manner the segments are kept rigid even in the absence of mica or other insulating material between them, and, in fact, this insulation would be to no purpose if particles of metallic dust were not liable to establish a contact between the various segments.



FIGS. 1 AND 2.

The insulating material is thus 0·025mm. less than the space separating the segments, which ensures a very close connection between the latter and the grooves. All the segments having exactly the same dimensions, it is not essential to turn the exterior surface of the commutator after they are placed in position.

In case of a section being damaged from any cause, it is an easy matter to take it out and replace it by another without interfering with the remainder, the operation only occupying a few minutes. This arrangement permits of the insulating material having a much greater thickness between the sections on the bushing, as also between the lugs supporting the wires.

In practice, one of the faces of the reserve segments is generally covered beforehand with a sheet of mica; and for an ordinary car motor the fixing of the commutator does not occupy more than half an hour.

Extensions.—Messrs. Easton, Anderson, and Goolden are making further extensions to their new shops at Erith, in order to expedite the carrying out of large contracts.

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

MULTIPHASED ALTERNATE-CURRENT SYSTEMS.

The reasons why the two and the three phase systems for the distribution of power and light have not been taken up at all in England are numerous, and no doubt to many engineers conclusive. We believe that local conditions make or mar a system, and attribute the great strides which the multiphase work has made in Germany and Switzerland to the abundant water power available. Without this the two nations in question would, in our opinion, still be greatly hampered in their electrical development by the cost of fuel.

Now, in Great Britain the number of electric supply stations which employ water power can be numbered on the fingers of one hand, and there is no station of any size using water power exclusively. Doubtless, in the more mountainous parts of the kingdom there is still a large amount of water power ready to be harnessed which will in time give scope to the electrical engineer. The question, however, is, Are the English electrical engineers right in ignoring these multiphase systems? Doubtless, some have in the past been misled by the hostile spirit shown by certain technical papers who found the multiphase work easier to damn than to understand. Also, we have suffered from want of practice. The engineers abroad have developed these machines largely by trial and error on successive machines made. From such experiments the single-phase motors have been developed, and we have yet to see a simple explanation of the principle on which these single-phase motors work. So the fact remains that, in spite of the eminent mathematical training which the Germans and Swiss have at their command, it has been the practical men working by rule of thumb who have developed this part of the industry. To return to the argument: the systems have not been developed here because of different local conditions depreciating their value, from which followed a want of interest in, and a consequent want of knowledge of, the capabilities of the subject. To give a bare statement of the facts. The three-phase system *per se* is essentially suitable for power transmission and distribution. It is the most economical, as far as the copper in the line is concerned, of any system used up to the present, and enables motors to be started under load. It is not suitable for lighting without modifications which do away with the economy in the copper of the lines. If lighting is attempted without the modification referred to, which is practically a fourth wire, the fluctuations in the voltage are at times excessive, due to the interconnected arrangement of the circuits in the generator. This difficulty vanishes when the two-phase system is used, with independent line wires for each circuit. Then the voltage of either circuit is independent of the load on the other, so that lamps can be freely used. In fact, the system lends itself to both lighting and power work conjointly. Both the two and three phase alternators and motors can be supplied at prices considerably below that asked for single-phase machines for the same output. There is no doubt but that single-phase motors will come to the fore and be employed

Digitized by Google

largely. Up to the present, however, they are all started on the two-phase system. Capacity or resistance in one circuit will give a difference of phase, and at the same time sufficient power current to produce the small starting torque sufficient to start the motor without load. This advantage of being able to start under load is greatly in favour of the duplex system, and we believe that such a system will be exploited in England within reasonable time for some district where there is a fair demand for power. Unfortunately, the backwardness of our engineers in these polyphase systems is unfavourably influencing our export trade. In the colonies and many foreign lands, where we are acknowledged as the makers of the best machinery for general and mining purposes, we are losing caste in the electrical section through want of this branch of our industry, so suitable for long-distance power transmission.

"One man's word is no man's word,
Justice needs that both be heard."

THE DUBIAU SYSTEM.

SIR,—You would oblige me by correcting a slight error in your article concerning the Dubiau tubular pump in your issue of July 26. It is there said that this new invention allowed of raising the quantitative efficiency of boilers from 50 to 15 per cent., instead of 50 to 150 per cent., as it should be.—Yours etc.,

Vienna, July 30, 1895. F. ROSS.

REVIEWS.

A Text-Book of Mechanical Engineering. By WILFORD J. LINEHAM. 772 pages. Published by Chapman and Hall, London, at 10s. 6d. net.

Mr. Lineham is the head of the engineering department at the Goldsmiths' Company's Institute at New Cross, and as the outcome of his experience as instructor he has compiled the well-written, well-printed, and well-illustrated book we have before us. It is divided into two parts: (1) workshop practice; (2) theory and examples. In the first part of the book Mr. Lineham makes a tour of the workshops through which a mechanical engineer must pass, hence we have chapters on casting and moulding, pattern-making and casting design, a brief chapter on metallurgy and the properties of metals, other chapters on smithing and forging, machine tools, marking off, machining, fitting and erecting, boiler-making and plate work. In the second part of the book Mr. Lineham deals with theory and examples. The book is illustrated with several hundred diagrammatic examples and 18 plates, which have an actual basis—*i.e.*, they are practical, and founded on practice.

The mathematics employed in this second portion are not of an advanced character. They involve simple equations, fractions, and the use of tables of sines and logarithms. Mr. Lineham has taken a step in the right direction in adopting an uniform synopsis of lettering in his formulæ. The student or reader, therefore, having once grasped the equivalent of a particular letter should avoid the puzzles or pitfalls that attach to varying meanings to particular letters such as may be found in some treatises.

We have not quite made up our mind as to what kind of man the mechanical engineer of the future is likely to be. Most of us who come in contact with the responsible managers of large industrial undertakings have heard laments from time to time of the want of a millwright of the type that flourished up to the seventies. The man of many capacities and ability to manipulate all kinds of hand tools is being converted into a machine-minder.

With the increasing number of machines, with greater and greater diversity of machinery, higher mental capacity will, no doubt, be demanded of the individual labourer. There promises, furthermore, to be a rearrangement of the officials of industrial enterprise, until we shall be classified as either privates, corporals, captains, colonels, or generals of productive industry. Such a book as Mr. Lineham's will serve a useful purpose, whatever view may be taken of the right way to teach or to bring up a mechanical engineer. We take it that those who have thought, or who have formed opinions upon this subject, are agreed that every man should be taught the principles underlying his trade, although there may be differences as to when and where the necessary instruction shall be administered. Mr. Lineham's book serves to give ideas, even where the operations he describes are not practicable in a technical college, as, for example, the process of blocking out a three-throw crankshaft.

The book is somewhat weak on what is perhaps its least important side—viz., metallurgy. It is, however, at least desirable that it should be accurate and not misleading. In the second edition Mr. Lineham should alter a few points that we will briefly indicate. In Chapter I. the pig-iron numbers should run from one to eight, and not in inverse order, as stated. Both the scientific and the commercial practice takes the most open grey pig as No. 1, by which the higher numbers are graded. The opening line on page 2 says "most of the impurities disappear in the blast furnace." As the context deals with pig iron, the statement is inaccurate. What Mr. Lineham doubtless means is that metallic iron is not found in the free state, but that it is freed in the blast furnace from the silicious or argillaceous impurities with which it is combined in the ironstone or iron ore. As a fact, the metallic iron in its molten state picks up impurities in its passage down the blast furnace. It is for this reason that when it emerges from the blast furnace as cast iron or pig iron, it requires after-treatment to fit it for commercial uses.

The "table showing chemical composition of the three principal varieties of pig iron" is misleading. Mr. Lineham should state that pig iron is produced by cold-blast and by hot-blast process of smelting. All chemists are at fault in regard to accounting for the differences in results in after-use between cold-blast pig iron and hot-blast pig iron. In fact, no chemist to-day knows why it is that first-class pig iron produced by cold blast should do certain work which is apparently impossible to pig iron made by hot blast. Chemical analysis fails to account for the differences which are familiar to all practical foundrymen. The making of chilled and grain rolls for rolling mills may be taken as an instance. The making of locomotive engine cylinders from cold-blast pig iron presents another instance familiar to many shrewd observant locomotive engineers.

The analyses quoted by Mr. Lineham are unfortunate, inasmuch as they indicate very bad pig iron for most purposes. The origin of the iron is not stated; from the figures it is apparently common Cleveland iron. Mr. Lineham should expunge these from future editions. If he wishes to give pig-iron analyses, he should quote Nos. 1 2, 3, and 4, mottled and white of a first-class cold-blast pig iron, such as Blaenavon, Farnley, Lilleshall, or Lowmoor, and state the purposes for which each variety or number is recommended. He might then give particulars of some of the best hot-blast foundry iron, such as Nos. 1 and 3 Coltness, Calder, or Gartsherrie, and if he thought well, by way of contrast, analyses of Nos. 1 and 3 Cleveland.

The brief descriptions of the different numbers of ordinary pig iron towards the end of the first chapter are more useful. But Mr. Lineham may add to the value of his book if he briefly gives a description of the influence of the most common metalloids when combined with iron in some more certain way than on page 73.

On page 80 there is a slip in which ingots of mild steel are spoken of as being *piled* and rolled to produce a fibrous steel. Ingots of steel are never piled. This is a feature peculiar to the manufacture of wrought iron from puddled bars. The same paragraph states that if ingots are required for steel castings, they may be "remelted in suitable quantities, etc." If this were physically possible, it is never done, and would be economically disastrous.

Digitized by Google

The first chapter of the book dealing with ironfounding illustrates an excellent teaching method. It first describes the melting of the crude iron (pig iron). A sketch in section is given of a cupola; then various examples of open sand, loam, and dry sand moulding are described with plain and appropriate illustrations. The moulding of various typical articles is described, sketches of the moulders' tools are given, and an illustration of a brass-melting furnace also appears.

In the second chapter the art of "pattern-making" is explained in a practical manner. The first chapter has intimated the work to be done. The second chapter proceeds to describe how it should be done. The difficulties attendant upon the crystallisation and warping and shrinkage of castings are explained. From the foundry, where molten metal is cast or poured into moulds, it is appropriate to step into the smithy. Mr. Lineham illustrates different types of smiths' hearths. Sketches are given of different air-blast producing machines, and a large plate shows an arrangement for an engineer's smithy. A series of plain sketches shows the various tools used in the smithy, not only hand tools, but also mechanical appliances, such as a steam-hammer, an "Oliver," and a stamping press. The method of manufacture of various small pieces of smithed work is followed out with sketches of the progress of the work through its various stages.

This is followed by the description and illustrations of the process of making different forgings under the steam-hammer, such as a single-webbed crank, a bell-crank lever, a double-webbed crank, and the manufacture of a bent crank in stamping dies. A coloured plate shows the various temperatures at which steel for various tools should be quenched to obtain appropriate "tempers." In dealing with forge proper, the author describes the manufacture of a large crankshaft under a double standard steam-hammer.

The author then passes on to machine tools. We notice a remark in the opening paragraphs which is characteristic, and to which we call attention, so that it may be corrected or qualified in future editions. Mr. Lineham says, "A thorough knowledge of these machines is necessary, so as to appreciate their capabilities and *enable us to design work to suit them.*" [The italics are ours.] We think the statement undesirable, without qualification. If new work is solely to be designed with a view to its being suitable for existing machine tools, there will be no development either in design or in the making of tools. The construction of the Forth Bridge will illustrate our point. The bridge was designed, but its successful construction was only rendered possible by the after-creation of special tools to get over all kinds of difficulties. A draughtsman engaged in a particular engineering establishment may be invited to arrange his designs to suit the capacities of that particular establishment. But even in this case the manufacturing facilities of a particular establishment may be extended by drawing upon larger works for parts of machinery that are beyond the capacity of a small establishment. This is a matter for discretion based on experience.

In the next edition we hope Mr. Lineham will make clear to his reading pupils that scrap iron is an uncertain and untrustworthy material for wrought-iron forgings, which are better when made from new iron in the Best-Yorkshire faggotted method. Some increase in tenacity may be expected from wrought iron, "especially the shearings of plates from the boiler yard" when "worked over and over again," but this is not explained by a reference to the quality of iron that has been "but once puddled" (page 134). All iron is, strictly speaking, but once puddled. The puddling furnace is an important and valuable apparatus. If the cast iron and the fuel are good and suitable and the puddling has been properly done—that is, if the maximum amount of elimination of impurities from the iron has taken place—then with suitable after-treatment good wrought iron will result. But no amount of after-work will make good iron of material that has not been properly treated in the puddling furnace.

Perhaps the best feature of this book is the admirable examples given of the use of stress and strain diagrams and of graphical methods of solving mechanical problems. These common-sense applications appeal specially to the practical man, and often enable him to avoid unnecessary mathematic, and long calculations. The examples worked out are, as a rule, well chosen, and represent the class of work for which such treatment is wanted in every-day practice. Again, we must commend the most liberal way in which Mr. Lineham has illustrated his book by original sketches of the essential parts of the various machinery and tools described. We should be pleased to see a large amount of space devoted to electrical problems and methods of power transmission. The information given at present is correct but scanty.

In future editions we hope Mr. Lineham will give a leaf-wide margin to the one or two amongst the folding plates that at present cannot be examined as a whole when the book is closed or when some page is under perusal other than that against which the plate appears.

We have examined the book with considerable pleasure. It is one that will prove of value to the young student as well as to the older engineer who has not had the advantage of systematic training in the *technique* of his calling. Carefully revised from time to time, we have no doubt this work will prove a standard text-book on mechanical engineering, for it is worthy of a place on the bookshelf of everyone interested in mechanical engineering.

NIAGARA FALLS AT WORK.

Prof. George Forbes has sent the following letter to the *Times*: "Your New York correspondent lately announced the successful commercial delivery of electric current from the great 50,000-h.p. generating station at Niagara Falls to the first consumers who use it for making aluminium. I also have received reports of the thorough success of the practical working, and it will be interesting to many of your readers to know wherein the novelty of the work consists, and the value of the results to the whole world. When I designed the 5,000-h.p. dynamos the largest in existence were of 1,500 h.p. The transformers which we employ, as well as other machinery, are also of far greater magnitude than any previously made, and this is part of the reason why the cost of these works is far below what any other engineer has been able to approach. There was nothing experimental in going to these large sizes; the nearest approach to experimental work was when I settled upon the machines for converting alternating into continuous current for the aluminium works, and these have now justified my choice. Such machines on a small scale were shown by Schuckert at the Frankfort Exhibition of 1891; but I took upon myself a great responsibility when making the first commercial use of them on so great a scale—four machines, each of 150 volts and 2,000 amperes. I selected as manufacturers the General Electric Company of America, and they deserve the greatest credit for the result. This company has also made some novel and excellent machinery which enables us to supply electrical energy at variable pressure to the 1,100-h.p. electric furnaces of the Carborundum Company. I will not refer to matters which I had to arrange for, but which are not yet completed. These include transmission of electric energy to Buffalo and its distribution; also the machinery for adapting the current for arc lights, for incandescent lights, for electric tramways, and for factories and mills. I mention these only to show the variety of requirements which had to be met, with strict attention to cost. Any customer may now ask either for continuous or alternating current at any fixed electrical pressure, or even at a variable pressure. My solution of the problem lay in (1) the selection of alternating currents, and (2) the reduction of speed of alternations as low as was possible, and (3) additional safety was ensured by my refusal to allow live circuits to be suddenly opened or closed. If this last policy be not continued, the directors will have themselves to blame for trouble which must arise. At the time when I decided upon alternating currents (which had not then been practically used for power purposes), many predicted failure, and some (including my friend Lord Kelvin)

Digitized by Google

have continued to do so. Again, when I adopted low frequency it was so generally condemned that I claim some foresight in having recognised its merits. I predicted low cost, high efficiency, and increased safety as the results of low frequency, and in practice I have been altogether confirmed. The price charged (with handsome profit) is half a farthing per Board of Trade unit, for which English companies (under more difficult conditions, it is true) are charging about 6d., and from the time of the inception of this gigantic and novel plant until its commercial working at the present time there has not been a single hitch or mistake to correct. The Niagara Company make a greater profit by not going to great distances, as it costs them less to supply it near at hand. There is no difficulty or experiment in going to great distances; it is merely a question of expense and of the value of power at the place to which it is transmitted. There are plenty of places in the world where it will pay well to carry electrical energy 400 to 500 miles. I have no hesitation in saying that the low cost and perfect success, practically and commercially, of the Niagara works open a new era in the world's industrial evolution."

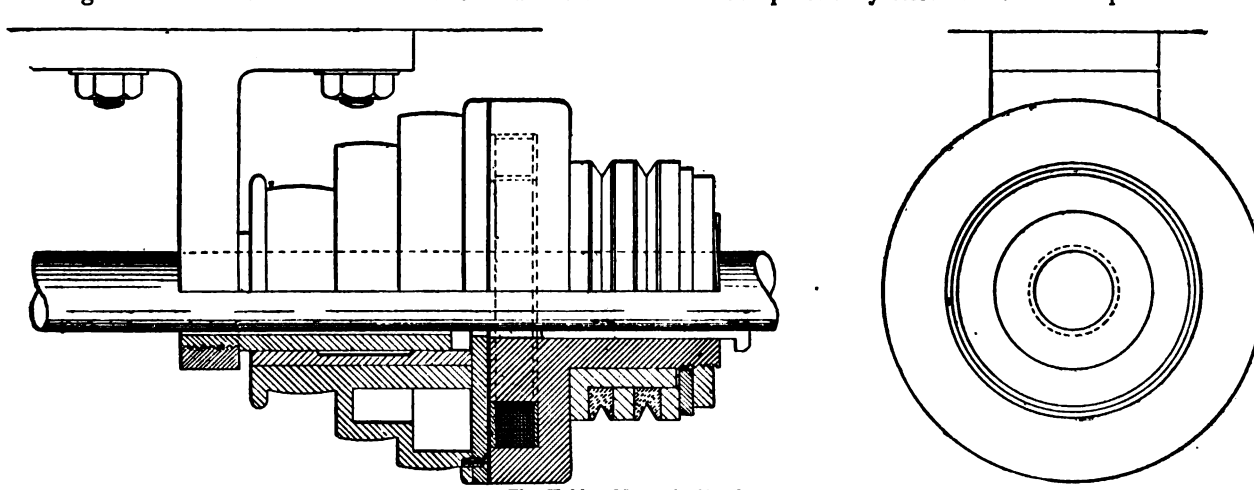
Lord Kelvin has since written as follows: "A letter by Mr. George Forbes in your yesterday's issue contains the following statement: 'At the time when I decided on alternating currents (which had not then been practically used for power purposes) many predicted failure, and some (including my friend Lord Kelvin) have continued to do so.' This is not correct, so far as the inclusion of my name is concerned. It is true that I advised the directors not to adopt the method of alternate currents; and the correctness of my advice is now illustrated by the fact that in the first practical use of the power it has been necessary to transform from alternate current to continuous current for the electrolytic smelting of aluminium. In giving my advice to the directors I told them that they could certainly succeed with alternate current, but much better with continuous current."

To Lord Kelvin Prof. Forbes replies: "If Lord Kelvin were at home, with his documents to refer to, he would not have written the letter published in the *Times* to-day. On looking through his Press copy-book, he will nowhere find that he 'told them' (the Niagara directors) 'that they could certainly succeed with alternate current.' On the contrary, he will find copy of a cablegram, in the summer of 1892, to these directors, declaring my policy of using alternating currents to be a fatal mistake or a disastrous mistake. He will also find the same view supported in a lengthy letter which he wrote at the same date. He will also find that in his letter of November, 1894, he referred to this attempt to save them from disaster. Besides these specific occasions on which he volunteered this advice, he took further action in the same direction at various times. This was embarrassing to the officers of the company, and they did not disregard the advice of an authority so eminent without finding sound reasons to justify their conduct, which I need not mention here. As to Lord Kelvin's suggestion, in the letter published to-day, that it would have been better to distribute to all customers the current required by the Aluminium Company (150-volt continuous current), I can at present only state that it is impracticable, and ask 'how about the 110 volts required for incandescent lighting, the 500 volts required for tramways, the 2,000 volts for arc lights, the 10,000 volts required for transmission to Buffalo, the alternating current required by the carborundum electric furnaces, and so forth?' Nearly everyone will now admit that the alternating current alone solves the problem well and economically."

Prof. Silvanus P. Thompson has also joined in the fray. He says: "Lord Kelvin's prepossession in favour of continuous currents, as against alternating currents, is not supported by modern electrical practice, save for the restricted purposes of electrolytic decomposition. On the contrary, for nine-tenths of all other purposes the advantage is found to lie on the side of alternating currents wherever the distance of transmission exceeds a few hundred yards. Lord Kelvin points to the use at Niagara of a special commuting machine to transform alternating currents to continuous, for a certain electro-metallurgic process, as though the fact that it had been necessary to add this adjunct condemned the use of alternating currents. It proves, however, the precise contrary. All the so-called continuous-current dynamos really generate—as Lord Kelvin knows well without any reminder from me—alternating currents, which are then commuted into continuous currents by a costly mechanical device called a commutator affixed to each machine. It is now recognised by electrical engineers that for nine-tenths of ordinary purposes, such as electric lighting and transmission and distribution of power, it is far better as well as cheaper not to add any commutator. By adding it most of the advantages of alternating currents are simply thrown away, and endless troubles are introduced by the sparks at the commuting brushes, to say nothing of other drawbacks. It would be a great pity if the immense influence of Lord Kelvin's opinion were to be used against progress."

THE HOLDEN MAGNETIC CLUTCH.

This apparatus has been patented by Major Holden, R.A., F.R.S., and Messrs. Drake and Gorham; it is found to be a great convenience at the Woolwich Arsenal, where it has been practically tried for some time past.



The Holden Magnetic Clutch.

Now that the advantages of electrical transmission of power in workshops in place of heavy belting and gearing have been recognised, the use of a magnetic clutch for each of the separate machines is bound to become universal, as it occupies far less space than the cumbersome fast and loose pulley arrangements, and is also less costly. The most economical results are obtained from a motor of fair size, driving a short line of countershaft, from which the machines are driven, in preference to small motors for each machine, which are more expensive in first cost, and necessarily less efficient in conversion of energy. A clutch of the size represented is capable of transmitting at 350 revolutions per minute 3 h.p. in regular work, the expenditure of

Digitized by Google

electrical energy being less than 20 watts during the time that the clutch is in action, at other times being nil. Simple forms of switch have been devised for starting and stopping, one form being similar to the arrangement at present in ordinary use with fast and loose pulleys, where pulling one cord starts and the other stops the machine, and another form which is actuated by one cord only, the switch being put on and off by alternate pulls of the cord.

A LABORATORY DYNAMO.

BY PAUL GIRAULT.

Laboratory practice often necessitates the employment of a continuous-current dynamo of high tension and small current. The solution generally adopted is to couple primary batteries or accumulators in series in sufficient number to obtain the voltage desired. This solution is very defective in all respects. The batteries take up a lot of room, are dear, require attention, which is at the same time troublesome and disagreeable, and necessitate minute attention to ensure good insulation; while as regards constancy of the voltage obtained, this is remarkable for its short duration.

On the other hand, a continuous-current dynamo properly worked out appears to fulfil all the required conditions. There is little space required, the price is low, cost of maintenance nothing to speak of, and as regards the voltage at the terminals it is easy to obtain perfect constancy, and to obtain all successive values up to the maximum of the machine by acting upon the speed and on the excitation. On account of these advantages, the laboratory of physical research at the Sorbonne, Paris, have added to their apparatus a high-pressure dynamo capable of giving 0·2 ampere at a pressure of 3,000 volts. This dynamo was ordered by Mr. Hurmuzeseu from the Cail factory in order to continue his researches in the variation of resistance of metallic salt solutions under the influence of high voltages.

Mr. Helmer designed this dynamo, which is illustrated by Figs. 1 and 2, giving a longitudinal and tranverse sections. The illustration only shows one machine, and the set supplied consisted of two such dynamos arranged on the same axis. Thus, in the complete set, four armatures were mounted on the same shaft, each capable of giving 0·2 ampere at 750 volts. Thus by suitable coupling it could supply

0·8	ampere	at	750 volts
0·4	,,	,,	1,500 ,,
0·2	,,	,,	3,000 ,,

These variations are very convenient from a laboratory point of view, and the generating of the pressure in four stages gives security. In case of accidents at least three of the armatures are likely to remain unaffected. The armature cores are built up of sheet-iron discs 12 mils thick, the outside diameter being 9⅞in., and the inside diameter 7⅛in. They are driven on the bronze cylinders by four keys, as shown in Fig. 2, and insulated from each other by paper. The width of the core when finished is 1 9in. The core is then insulated as follows: one winding of cotton tape, one of silk tape, then another of cotton.

The armatures are wound in 160 sections, each of 66 turns. The total number of turns, therefore, is 10,560. The conductor is ·0128in. diameter, and is wound in nine layers carefully insulated with mica. The armature when wound is placed in paraffin and heated up to 150deg. C., and a current is passed through the wires to heat them to ensure the wax getting into all the crevices. In this way a good insulation resistance has been obtained. The commutators are of copper, each having 160 segments, and a diameter of 8in. The method of construction is clearly seen from the diagrams, Figs. 1 and 2.

Magnets.—There are in the complete set two magnetic systems, each energising two armatures. The magnet and pole-pieces are made of soft steel. They are separately excited at 110 volts. There are in all two exciting coils for each magnet, and these are wound with a total of 1,856 turns of ·055in. diameter wire. The diameter of the bore of the poles is 10·6in. Each pole embraces an angle of 165deg. of the armature.

The speed of the machine is 1,500 revolutions per minute, and then about 3,000 ampere-turns are required in the exciting coils. The resistance of each armature is 128 ohms—the copper-resistance loss thus amounting to 3·12 watts. The mean induction in the armature iron is 12,150 C.G.S. lines per square centimetre. The calculated hysteresis loss equals 28·66 watts. That the machine was well able to do its work is shown by the adjoining test figures, when the rated speed was never reached.

THE MODE OF DEATH FROM ELECTRIC SHOCK.

Dr. J. Mount Bleyer, of New York, has advanced the view that death from electric shock is due to "dynamic apoplexy."

He describes the *post-mortem* appearances in a criminal executed by electricity in whom the bloodvessels of the trunk and limbs were almost empty, while those of the head and neck were distended with blood. The violent muscular contractions produced by electric shock, the *Lancet* says, naturally tend to alter very considerably the distribution of the blood in the various parts of the body, and it is very probable that great cerebral engorgement, with hæmorrhages into the brain substance, may commonly occur

Digitized by Google

in death from electric shock. The medical man who made the necropsy, however, would seem to overstate the case when he says that two quarts of blood escaped when the skull was opened. There is not room in the cranial cavity for that quantity. The immediate cause of death from electric shock is almost certainly due to stoppage of the heart, the injury to the brain here described not being an essential factor, though it may frequently coexist as a complication.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

BOARD OF TRADE REPORT.

We give below the report by the Board of Trade respecting the applications to and proceedings of the Board of Trade under the Electric Lighting Acts, 1882 to 1890, during the past year. The following is a list of the applications for provisional orders since the date of the last report (see *Electrical Engineer*, August 24, 1894), together with the title of order and description of area, the names of promoters, and how dealt with by the Board of Trade:

Alderley Edge Electric Lighting Order.—The Urban District of Alderley Edge.—The Urban District Council.—Order granted.

Bath Electric Lighting Order.—The City of Bath.—City of Bath Electric Lighting and Engineering Company, Limited.—The promoters failed to produce the consent of the local authority, and the Board of Trade directed that a local enquiry should be held. After consideration of the report made by the inspector appointed to hold the enquiry, the Board of Trade were of opinion that no reasons had been advanced sufficient to justify them in dispensing with the consent of the local authority, and refused to grant the order.

Bootle Corporation Electric Lighting Order.—The Borough of Bootle.—The Corporation.—Order granted.

Brechin Electric Lighting Order.—The Royal Burgh of Brechin—Scottish House-to-House Electricity Company, Limited.—The local authority consented to the grant of the order, subject to certain agreed conditions as to purchase, and the profits of the undertaking. The latter condition the Board of Trade was unable to sanction, and, as the local authority refused to modify the conditions, the promoters did not proceed with the application.

Carlisle Corporation Electric Lighting Order.—The City and Municipal Borough of Carlisle.—The Corporation.—Order granted.

Leigh Urban Sanitary Authority Electric Lighting Order.—The Urban Sanitary District of Leigh.—The Local Board.—Order granted.

Liverpool Electric Lighting Order.—Portions of the City of Liverpool and of the Local Government District of Toxteth Park.—Liverpool Electric Supply Company, Limited.—The Liverpool Corporation consented to the grant of the order; but the Toxteth Park District Council refused their consent. The Board of Trade, however, for the reasons stated in the special report made by them and presented to Parliament, decided to grant the order.

Llandudno Electric Lighting Order.—The Urban Sanitary District of Llandudno.—The Urban District Council.—Order granted.

Luton Corporation Electric Lighting Order.—The Borough of Luton.—The Corporation.—Order granted.

Margate Electric Lighting Order.—The Municipal Borough of Margate.—Municipal Electric Light and Power Corporation, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.

Montrose Electric Lighting Order.—The Royal Burgh of Montrose.—Scottish House-to-House Electricity Company, Limited. The local authority consented to the grant of the order, subject to certain agreed conditions as to purchase and the profits of the undertaking. The latter condition the Board of Trade was unable to sanction, and as the local authority refused to modify the conditions, the promoters did not proceed with the application.

Motherwell Electric Lighting Order.—The Burgh of Motherwell. The Commissioners of the Burgh.—Order granted.

New Windsor Corporation Electric Lighting Order.—The Borough of New Windsor and the Eton Urban District.—The Corporation of New Windsor.—Order granted.

Prescot, Huyton and Roby, Rainhill, Eccleston, and Whiston Electric Lighting Order.—The District of the Prescot Local Board; the District of the Huyton and Roby Local Board; the Townships of Rainhill Whiston, and Eccleston.—British Insulated Wire Company, Limited.—Order granted for the Urban District of Prescot. As regards the other districts included in the application, the promoters failed to produce the consent of the local authorities, or to satisfy the Board of Trade that it should be dispensed with, and the Board decided to exclude those districts from the order.

Radcliffe Electric Lighting Order.—The Urban Sanitary District of Radcliffe.—The Urban District Council.—Order granted.

Stirling Electric Lighting Order.—The Parliamentary Burgh of Stirling.—The Commissioners of the Burgh.—Order granted.

Pontypool Electric Lighting Order.—The District of the Pontypool Local Government.—Pontypool Electric Light and Power Company, Limited.—Order granted.

Salisbury Electric Lighting Order.—The City of Salisbury.—Salisbury Electric Light and Supply Company, Limited.—Order granted.

Southampton Electric Lighting Order.—The County Borough of Southampton.—Southampton Electric Light and Power Company, Limited—Order granted.

Swindon New Town Electric Lighting Order.—The Urban Sanitary District of Swindon New Town.—The Local Board.—Order granted.

Walthamstow Electric Lighting Order.—The Local Government District of Walthamstow.—The Local Board.—Order granted.

Winchester Electric Lighting Order.—The City of Winchester.—The Corporation.—Order granted.

Windermere and District Electric Lighting Order.—The Districts of the Urban Sanitary Authorities for Grasmere, Ambleside, Bo'ness, Windermere, and Kendal; the District of the Kendal Union Rural Sanitary Authority; the Districts of the Urban Sanitary Authorities for Ulverston and Grange; the District of the Ulverston Union Rural Sanitary Authority; a Portion of the District of the Lancaster Union Rural Sanitary Authority.—Windermere and District Electricity Supply Company, Limited.—The promoters failed to produce the consent of the local authorities for Ambleside and Kendal, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade omitted those districts from the order as granted. The Ulverston Urban District Council, the Ulverston Rural District Council, and the Grange Urban District Council pressed for an amendment of the purchase clause of the order, but the Board of Trade were unable to sanction the amendment, for the reasons stated in the special report made by them and presented to Parliament.

Worthing Electric Lighting Order.—The Borough and District of Worthing.—The Corporation.—Order granted.

THE COUNTY OF LONDON.

Battersea Electric Lighting Order.—The Parish of St. Mary, Battersea.—County of London and Brush Provincial Electric Lighting Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.

Newington Electric Lighting Order.—The Parish of St. Mary, Newington.—Same promoters.—Same result.

Notting Hill Electric Lighting Order.—A portion of the Parish of St. Mary Abbotts, Kensington.—Notting Hill Electric Lighting Company, Limited.—Order granted.

St. Olave Electric Lighting Order.—The District of the St. Olave District Board of Works.—County of London and Brush Provincial Electric Lighting Company, Limited.—Order granted.

Strand District Electric Lighting Order.—The District of the Strand District Board of Works.—Charing Cross and Strand Electricity Supply Corporation, Limited.—The local authority consented to the grant of the order, subject to certain modifications in its terms. The Board of Trade were unable to accept some of these modifications, but for the reasons stated in the special report made by them and presented to Parliament, they decided to grant the order.

Of these applications (29 in number) 14 were made by local authorities and 15 by companies. Five of the applications related to London.

Licenses.—The following application for a license has been received since the date of the last report, and has been dealt with in the following manner: The Salisbury Electric Light and Supply Company, Limited.—The City of Salisbury.—License granted December 6, 1894.

Of applications for licenses referred to in previous reports, that of the British Insulated Wire Company, Limited, was granted on October 8, 1894.

Appended to the report is a list of the provisional orders confirmed by Parliament (prior to the present session) and of the licenses granted by the Board of Trade since the passing of the Electric Lighting Act, 1882, showing those which have since been revoked or repealed.

LEGAL INTELLIGENCE.

WOODHOUSE AND RAWSON.

In the action Wood *v.* Woodhouse and Rawson, United, Limited, before Mr. Justice Vaughan Williams, on Wednesday,

Mr. Wright, for the official receiver and liquidator, said there was a summons by him asking leave to be given to institute proceedings, under Section 10 of the Companies Winding-up Act, against the directors and auditors, and that the costs be provided for by the receiver in the action out of the assets in his hands. The application came before this Court on May 16, and his lordship then directed that meetings of the debenture-holders should be held to ascertain their wishes with reference to taking proceedings. The opinion of counsel had been taken, and it was to the effect that the dividend declared in 1891 was to a very large extent paid out of capital, and that no less than £20,000 was recoverable in respect of that dividend, while other sums might also be recovered. The total debenture debt ranking for dividend was £160,000. Of that amount there were £65,500 first mortgage

Digitized by Google

debentures with 6 per cent. interest, £83,000 second debentures bearing 5½ per cent. interest, and £14,000 bearing 10 per cent. interest, the last being a specific charge on certain securities. Out the assets, other than those that could be realised by instituting proceedings, the receiver estimated that the 6 per cent. debentures would get 6s. 8d. in the £, or a deficiency in their security of £43,700. The 5½ per cent. debentures would get nothing, so that there was a deficiency of £83,000, and the 10 per cents., who had the specific charge, would get 17s. in the £. At the meeting 29 holders of the 6 per cents. (representing £36,300) were present, and nine, holding £3,900, voting in favour of instituting proceedings, and 20, holding £32,400, voted against. The 10 per cent debenture-holders voted unanimously against taking proceedings. At the meeting of the 5½ per cents. 50 were present, representing £34,423 out of £83,000. Fourteen, holding £8,421, were in favour of, and 36, holding £26,000, against taking proceedings. The position the official receiver took was that it was a debenture-holders' question, that they were entitled to the assets, and that there was nothing for the shareholders; but it was somewhat singular that the debenture-holders should have taken up this attitude.

His Lordship: I generally find that debenture-holders with security are against proceedings. Do you say they honestly voted that there should be no proceedings?

Mr. Macnaghten said he appeared only for the plaintiffs in the action, and he could not enter into their minds on this question. But the official receiver was chairman, and that was a guarantee that the meetings were properly conducted.

His Lordship: They may have come to the conclusion they did either because, notwithstanding counsel's opinion, they thought there was no good cause of action, or they may have thought it was too risky, and therefore not worth spending money upon, or they may have thought that those from whom the sums of money were to be recovered were not worth powder and shot.

Mr. Macnaghten said his client, who was at the meeting, instructed him that all these views were expressed.

His Lordship said he would assume, then, that they acted from such motives as they had suggested, and they all came under the same category. They did not want proceedings; but if the unsecured creditors thought fit to realise those assets it would not hurt the debenture-holders one bit, and, therefore, he expected them to assent to it. If they did not, he would feel bound to take the conclusion they had come to as one not arrived at in good faith.

Mr. Macnaghten said that the only point was whether proceedings should be taken at the expense of the debenture-holders.

His Lordship said he would take the opportunity of testing their good faith.

Mr. Macnaghten: And do you call a meeting of these people?

His Lordship directed that there should be a meeting of all three classes of debenture-holders at one time to know whether those who would not take proceedings would abandon their claim to any assets recovered in proceedings instituted by others, the official receiver to take the chair, and this summons to stand over until the result of the meeting was reported to the Court.

PRESCOT ELECTRIC LIGHTING.

On Monday, in the Queen's Bench Divisional Court, Mr. Baron Pollock and Mr. Justice Wright heard the case of the British Insulated Wire Company, Limited, *v.* the Prescot Urban District Council. It was a special case, which raised the short point as to whether a contract was void or not as construed by the light of the one hundred and seventy-fourth section of the Public Health Act, Sub-section 2. Mr. Lawson Walton, Q.C., M.P., and Mr. R. N. Arkle appeared for the plaintiffs, and Mr. Otto Danckwertz for the defendants.

Mr. Arkle said the question for decision was whether that contract between the parties was void by reason of its not containing a pecuniary penalty in respect of the non-performance of any of its conditions. The contract was made in November, 1892, and it was provided that the company should efficiently light the streets within the district of the Local Board by means of electricity for a period of five years from January 1, 1893 The lamps were to be stationed in the streets as approved by the Local Board, and were to be laid down and kept in repair at the expense of the company. One-half the incandescent lamps should be lit during the hours of darkness all the year round, the other half to be lit from dusk to midnight from August 25 to May 25 in each year, and the arc lamps were to be lit from dusk to midnight, no notice being taken by the company of moonlight or other causes which would tend to enable them to depart from a fixed course of electric lighting. The Local Board were to pay £350 per year, payable quarterly, in consideration of such lighting, and the company was to indemnify the Local Board in respect of all actions in regard to the works and the light. The action was brought to recover £78, which included three quarterly payments of £87 respectively, and the balance was made up of three sums for extra lamps. The contract was duly executed, and the seal of the Board affixed. These facts were agreed, and the only point between the parties was whether the absence of a penalty clause in the contract vitiated the contract. Learned counsel's submission was that the clause in the Act regarding this was merely directory, and did not vitiate the contract. The point had never been decided before, though it had been raised twice.

Without calling upon Mr. Danckwertz to reply,

Baron Pollock said he did not see how the Legislature intended that the question of penalty should be treated as a merely voluntary matter. Sub-section 2 was not merely directory, as it specified that a penalty should be stated in the case of the contract not being performed.

Mr. Justice Wright concurred.

Judgment was thereupon entered for the defendants with costs.

COMPANIES' MEETINGS AND REPORTS.

ELECTRICAL POWER STORAGE COMPANY, LIMITED.

The sixth ordinary general meeting of this Company was held at 4, Great Winchester street, E.C., yesterday, Mr. John Irving Courtenay in the chair.

The **Chairman** said he was glad to meet the shareholders again and to be able to say that the directors recommended the same dividend as last year—viz., 5 per cent. They had also been able to increase the reserve fund by the sum of £2,684. 12s. 11d., so that that account now stood at the satisfactory figure of £12,000. A larger sum than usual had been spent at Millwall in plant and tools—viz., £1,696. 10s. 8d.—which included new boilers, engine, and building extensions. The directors had reduced the selling prices of the Company's storage batteries. They fully appreciated the exertions of the manager (Mr. Frank King) and his staff, who had by their unremitting attention to maintaining the high quality of the Company's batteries, and at the same time reducing the cost of manufacture, enabled the directors to meet the severe competition in this most practical and telling manner. He concluded by moving the adoption of the report and accounts.

Sir Daniel Cooper, Bart., G.C.M.G., seconded the resolution, which was carried unanimously.

Mr. James Pender, M.P., was re-elected a director of the Company, and the auditors, Messrs. Meston and Co., were also re-elected.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

The annual general meeting of the shareholders of this Company was held on Monday at the Cannon-street Hotel, under the presidency of the chairman, Mr. James Staats Forbes.

The **Chairman**, in moving the adoption of the report and accounts, which were printed in our last issue, said that they now had the results of the second year of Company's working since the expiry of their patents. That expiry took place at the end of the first three months of the preceding year, when they were immediately subjected, as they had fully expected, to rather severe competition from a great many quarters, including their German friends, who were pretty astute and persevering. The shareholders would have to extend to the directors and managers of their properties their confidence, and believe that their daily knowledge of the circumstances of the business would enable them, with prudence and discretion, to secure the interests of the proprietors without putting on them the necessity of making public in too great detail the many items which made up the business. He need scarcely tell them that during the time of the protection of their patents they were in a very advantageous position, being enabled, as they were, to fix their own prices. As the period approached for the expiry of the patents they made prudent arrangements for meeting the severe competition which was likely to arise, and that those arrangements were effectual was proved by the results of the following nine months, when they were able to pay to the shareholders a reasonable dividend. In the second year following the accentuation of the competition they had to face a very considerable reduction in the prices of the articles they produced, but the satisfactory feature of that year seemed to be that notwithstanding the severity of the competition they were able to show a larger volume of output. They had sold more lamps during the year than in the preceding year; but inasmuch as during three months of the preceding year their prices continued high, owing to the non-expiration of their patents, the money results were altered, but, being altered, they still left such a margin of profit as made the payment of a 5 per cent. dividend for the year perfectly easy, rational, and wise. They began the year with stock on hand to the value of £87 768, and at the end of the year that stock had increased to £95,983. The wages, purchases, etc., had amounted to £85,112. Notwithstanding the very severe competition, notwithstanding that natural desire which prudent people had to substitute a cheaper article for a dearer one, they had been able to maintain their business, to improve their character, and to learn a good deal. They now knew a good deal more accurately than before the wants of the public, with the result that the volume of their business had increased, and if the receipts had diminished slightly as a consequence of prices having fallen, the quantity had increased.

The **Earl of Lichfield** seconded the motion, which was carried.

The **Chairman** moved: "That a dividend be, and is hereby, declared on the 'A' shares of the Company of 1s. 6d. per share on the 89,261 ordinary shares, £3 paid; of 2s. 6d. per share on the 5,000 £5 fully-paid shares allotted to the Edison Electric Light Company, Limited; and of 2s. 6d. per share on the 12,139 £5 fully-paid shares allotted to the Swan United Electric Light Company, Limited; being, together with the interim dividend paid on March 20, 1895, 5 per cent. in respect of the year ended June 30, 1835. All to be distributed in accordance with the provisions of Clause 87 of the articles of association, less income tax."

This was seconded and carried.

The retiring directors (the Earl of Lichfield and Mr. Ernest

Digitized by Google

Villiers) were reappointed, as were also the auditors (Messrs. Welton, Jones, and Co.).

An extraordinary general meeting followed for the purpose of considering the following special resolution, of which formal notice had been given: "Resolved that the articles of association of the Company be altered by striking out Article 87 and substituting therefor the following article: '87. The amount from time to time declared by the Board as available for dividend, including the amount, if any, recommended by them to be withdrawn from reserve for equalisation of dividends shall be applied as follows: (1) There shall be first set aside thereout a sum equal to a preferential cumulative dividend of 7 per cent. per annum on the aggregate amount for the time being paid or credited as paid on the 'A' shares. (2) Out of the sum so set aside there shall be paid a preferential cumulative dividend at the rate of 5 per cent. per annum on the amounts paid or credited as paid on the 'A' shares without distinction. (3) Subject thereto, there shall be paid out of the sum so set aside a further cumulative dividend at the rate of 2 per cent. per annum on the amount paid or credited as paid on the 'A' shares, provided that until all the 'A' shares be fully paid, no 'A' share, whether fully paid or not, shall, for the purpose of this sub-section, be deemed to have paid up on it more than the amount paid up or called up upon the 'A' shares for the time being having the least amount called up or paid thereon. (4) The balance of the sum so directed to be set aside shall be carried to the reserve fund. (5) The residue of the amount declared to be available for dividend after setting aside the sum mentioned in Sub-section 1 shall be applied in payment of dividends *pari passu* on the accounts paid up or credited as paid on the 'A' and 'B' shares, but so that for the purposes of this sub-section the amounts to be deemed paid up on the 'A' shares shall be ascertained as in the case of Sub-section 3.'"

The resolution was carried on the motion of the **Chairman**, seconded by the **Earl of Lichfield**.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The twenty-second ordinary general meeting of this Company was held on Monday at Winchester House, E.C., Mr. Charles G. Mott presiding.

The **Chairman**, in moving the adoption of the report, stated that although they were able to recommend a slightly increased dividend, the result of the working of the past half-year had been somewhat disappointing. They began the period very well, the traffic showing a steady and regular increase, and they had hoped that at the end of the half-year they would have a very satisfactory report to present. As soon, however, as the fine weather set in at the end of March their traffic began to fall off, with the result that at the end of the six months very little of the improvement remained which they had in the first part of the period under review. All the railways, however, or nearly all of them, had from one cause or another shown a heavy decrease in the last six months, and most of them were reporting decreased dividends. The receipts from passenger traffic, other than season-ticket holders, showed a decrease of £335 last half-year compared with those of the June half of 1894, but there had been an increase in the receipts from season tickets of £482. Their expenses exhibited a net increase of £29. The increase of £106 in passenger duty was owing to the advance they made in their fares from Stockwell, but these fares had now been reduced again, and they were no longer liable for passenger duty on them. The balance carried to net revenue account was £9,381, to which £47 for interest and £950 brought forward had to be added. After paying their debenture interest (£3 959) and the preference dividend (£1,912) they were enabled to recommend a dividend on the ordinary stock at the rate of 1½ per cent. per annum, leaving a balance of £964 to be carried forward. The working expenses had been 61·5 per cent. of the receipts against 61·69 per cent. in the June half of 1894, and if they took off the cost of the lifts, as they generally did, the amount was about 52 per cent. This was a fairly low rate of working, but they hoped to get it very much lower. The locomotive expenses per train mile had been 6·10d. in the past half-year against 6·22d., and if they deducted, as they had done before, the carriage of coal, the expense per train mile came out at about 4¾d. The receipt per train mile had risen from 2s. 1¼d. to 2s. 2½d. this half-year, owing to the increased fares charged. The receipts per passenger had also risen from 1·61d. to 1·82d. They had carried during the half-year, exclusive of season-ticket holders, 3,113,000 passengers, showing a decrease of 270,000 as compared with the number conveyed in the corresponding period of 1894, but this had been compensated for to some extent by the higher fares and the increase in the receipts from the season-ticket holders. The falling off in the number of passengers was no doubt partly owing to the increased fares charged, and partly to the extraordinarily fine weather in the last three months of the half-year. Their experience of the motor-car train which was running at the date of their last meeting had been satisfactory so far as it went, but it had not made them very anxious to convert the rest of their stock. It would be a very expensive operation, and would take a long time, and there were various reasons why they thought it should not be carried out at present. The most important of these reasons was that at the last meeting they determined that they should go on with the extension as far as Finsbury-circus. When that extension was completed they would be able to run heavier trains, carrying very many more passengers, and probably they would endeavour to run these trains more rapidly than they did at present. All this would require very much more powerful motors, and they thought it better to postpone any further proceedings in this direction until the extension was completed. Their engineer had at last devised a plan by which he could convert the King William-street Station into almost a replica of the Stockwell Station, having a centre platform and two lines of rails on each side, so that they would be able to work three or four trains per hour more into it than they could at present. This would give them about 25 per cent. additional accommodation. They were endeavouring in every way they could to reduce their expenditure. They were now running two engines to drive the dynamos which worked the line, but there were times in the middle of the day and on Sundays when a great deal of the power produced was wasted, and they had ordered a smaller engine and dynamo to work in conjunction with one of the larger engines and dynamos at slack times when the power of the two large engines was not required. This would diminish the cost of working to some extent. They were also proposing to run an additional number of two-coach trains during the quieter hours of the day and on Sundays and to purchase additional coaches for that purpose. They had done something towards improving the lighting of the carriages in the past half-year, but it was not yet satisfactory. They were going to make other experiments with the view of still further improving the illumination of the trains. The plans for the extension to Finsbury circus had at length been devised by Mr. Greathead, and they were now in negotiation for the sites of the stations. The Bill for extending the time for the Clapham extension had received the Royal assent, and this would give them another three years for completing that portion of their undertaking.

Mr. Sampson Hanbury seconded the motion.

The **Chairman** said, in reply to an enquiry, that an extension to Moorgate-street Station was in contemplation.

The report was then unanimously carried, as was also a vote of thanks to the chairman.

NATIONAL TELEPHONE COMPANY, LIMITED.

The ordinary general meeting of the above Company was held at Cannon street Hotel on Friday last, Mr. J. Staats-Forbes occupying the chair.

The **Chairman**, in moving the adoption of the report, stated that the increase in the income of the past half-year, to June 30, was £33,963, as compared with the income of the corresponding period of 1894. The working expenses also showed a considerable increase, but not much out of proportion to their larger business. The net result, after deducting £35,263 for the Post Office royalties, was a profit balance of £151,703, or an increase of £11,169 over the balance shown a year previously. The rentals carried forward for unexpired terms of running contracts amounted to £390,978, or £45,619 in excess of the amount shown at the corresponding period of 1894. They proposed to pay the usual dividends on the first, second, and third preference shares, less income tax, and 5 per cent. on their ordinary shares, free of income tax. They proposed to carry to the reserve fund £35,000 out of the balance then remaining, and this would leave £3,288 to be carried forward. For the first time their net income had been arrived at after charging interest out of revenue upon their large reserve fund. If the shareholders approved the directors' recommendation, the reserve fund would in their next balance-sheet stand at £314,500. The work of metallic-circuiting London had been going on quietly now for some time, and at great cost, but happily it was approaching completion. He regretted that the change had caused a great derangement in their machinery from time to time, to the serious annoyance of many of their subscribers. This, however, had been unavoidable. The example of Berlin was often held up to them, but he knew Berlin very well. Everything was regulated there, and the people knew how to wait their turn when they desired to use the telephone. Every subscriber in London, however, thought that he had the fee-simple of the whole apparatus at his command—that he alone had to be served. Reference was made in the report to the formal agreement with the Post Office for the acquisition by the Department of the company's trunk lines. They had bowed to the inevitable, and made the best terms they could, and he believed that they would prove to be extremely good terms if the Government and the Post Office authorities were as loyal as the Company. There was not the slightest reason to doubt that they would be, and he ventured to say that, for the revenue of the country, for the efficiency of the telephone service, for the public interest, and for the interests of the Company, it would be the best combination that could have been made, because the Post Office were enabled to take risks in connection with the extension of the system which the Company would not be inclined to take, but of which they would have the benefit, while they would themselves be left free to develop what was their more special business—the conduct of the exchange work in the great areas. The heads of the agreement with the Post Office were signed more than two years ago, but they had been necessarily subjected to a great deal of discussion. In virtue of the agreement, the Company had made considerable sacrifices, for he had no doubt that if they had been allowed to go on under the old arrangement they would have made a more substantial advance in the development of the telephone system. The agreement, with the Company's consent, after being laid on the table of the House of Commons, was eventually referred to a special committee, who sat for a considerable time and met on several occasions. He believed that everything that could be alleged against the Company was brought against them before the committee, but the Company's turn came, and then they gave the facts, the figures, and the arguments on their side. Owing

to the dissolution of Parliament the committee's labours came to a close, and in their report they had recommended that a committee on the same subject should be appointed next session "to consider and report upon the evidence already taken, and, if necessary, to take further evidence." Out of the 15 members who sat on the committee 10 or 11 had been re-elected members of Parliament, and he only hoped that the enquiry would be finished speedily, because until then they would not know where they were.

The motion was passed.

The Right Hon. Lord Harris, G.C.S.I. G.C.I.E., has been elected a director and vice-president to fill the vacancy caused by the resignation of the Right Hon. the Lord Balfour of Burleigh; and Sir Henry George Calcraft, K.C.B., has been elected a director to fill the vacancy caused by the resignation of Colonel R. Raynsford Jackson.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

The ordinary half-yearly meeting of the shareholders of this Company was held on Friday last at Winchester House, under the presidency of the Marquis of Tweeddale (chairman of the Company).

The **Chairman**, in moving the adoption of the report and statement of accounts, said that for three half-years he had had to deplore a falling off of traffic receipts, the decrease in July last having been £16,791, while in January of the present year it was £6,948. On this occasion, however, he was happy to be enabled to report that there was an increase of £9,382, which, although not a very large addition to the gross income of the Company, was, at any rate, a step in the right direction. It was also an indication of a welcome return to confidence in business circles, which probably meant a much greater increase in the future. This prospect had certainly been confirmed by the receipts of the current month, which showed the largest increase over the months of the preceding year that had been received in the course of the present year. It was, however, disappointing that the whole of the half-year's increase was not available for dividend. This was in consequence of the repairing ship "Minia" not having been enabled to earn as much as she did during the corresponding period of last year. The decreased earnings thus accounted for amounted to £2,550. On the other hand, the expenditure showed one or two satisfactory features, there being a decrease of £1,342 under the head of repairs of cable, though, on the other hand, there was an increase of £1,009 under the head of expenses at stations and at the head office, which brought the net decrease to £333. This, however, though apparently a small sum, was significant when it was remembered that the decrease under this head last year was no less than £4,460, it being very satisfactory that that large amount should have been decreased still further. The directors had, before declaring the net profits, set aside the sum of £12,000 for the renewal fund, leaving a balance of £74,331. One important matter was the condition of the company's cables, and he was glad to be enabled to state that they were in first-rate working order. The new cable was in as good a condition as it was expected to be in with regard to its power of transmission, while the cables of 1873 and 1874 were also in excellent electrical condition. The same statement might be made with regard to the 1880 cable. There was, he was glad to say, a slight increase in the dividend to be declared, but although it was only slight he thought that as the Company had had a good many lean years they were now entitled to look forward to something better in the future. The French case was still *sub judice*, but the directors, under the advice of eminent counsel, have entered an appeal which they believed afforded a reasonable prospect of a successful issue.

Mr. F. A. Bevan seconded the motion, which was agreed to.

GLOBE TELEGRAPH AND TRUST COMPANY, LIMITED.

The twenty-second annual meeting of the shareholders of this Company was held on Friday last at Winchester House, the Marquis of Tweeddale occupying the chair.

The **Chairman**, in moving the adoption of the report, said that the receipts of the Company for the past year, with the small balance carried forward, were £179,992, out of which had been distributed £123,361 in interim dividends. The directors now recommended the payment of a final dividend on the preference and ordinary shares, making altogether a total dividend of 6 per cent. upon the former shares, and 4⅛ per cent., against 4½ last year, upon the latter. There was a decrease in the receipts of £5,611, which was attributable to three causes: in the first place, there was a smaller dividend received from the Anglo-American Telegraph Company in the first two quarters of the current year; in the second place, a smaller return from their investments in the Direct United States Cable Company; and there was the paying off of the Direct Spanish Company's 6 per cent. debentures. Looking at the depression that had been prevailing during the last few years in commercial circles, he considered the distribution to be a fair one. Referring to the Company's investments, he pointed out the increasing market value of their shares, and stated that while the paid-up capital was £3,602,690, the value to-day stood at £4,296,395, showing the very handsome surplus of £793,000. He thought the shareholders would agree that this was very satisfactory.

Lord Sackville A. Cecil seconded the motion, which was agreed to.

Sir J. Pender and Mr. Brodrick were re-elected directors.

CHILI TELEPHONE COMPANY, LIMITED.

The annual general meeting of this Company was held on Tuesday at Winchester House, Mr. Geo. Keith occupying the chair.

The **Chairman** said the shareholders would see with satisfaction that, despite the adverse circumstances that had prevailed in Chili during the year, the Company had done fairly well, and they were able to declare a dividend of 2½ per cent. per annum. A small addition to the tariff had caused 704 of their old subscribers to withdraw, but they had been replaced by 676 new ones, while at the same time the Company had opened up new ground in country districts. The gross receipts had improved by about 10 per cent., and the net profits had been £6,013, as compared with £3,528 last year. The rate of exchange was gradually becoming more favourable for the Company, and in that respect their prospects were much brighter, the result of the Conversion Bill and the adoption by Chili of a gold standard. He moved the adoption of the report and accounts, and the motion was seconded by **Mr. Frank W. Jones** and carried.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

An extraordinary general meeting of this Company was held at 73, Lombard-street, E.C., on Monday for the purpose of receiving the first annual report of Mr. Charles Fitch Kemp, the voluntary liquidator to the concern, which was published in our last issue. Representatives of the Press were not admitted to the meeting.

RAND CENTRAL ELECTRICAL WORKS, LIMITED.

The statutory general meeting of the above Company was held on Wednesday at Winchester House, Old Broad-street, E.C., Sir Charles Rivers Wilson occupying the chair.

The **Chairman** said that the Board, which was properly constituted, had every expectation that the hopes held out when the Company was formed would be amply realised. The contractors had arranged to complete their portion of the work within 18 months from May 3 of this year—that is to say, they would hand over all the appliances not later than November 3, 1896. Messrs. Price, Waterhouse, and Co. were appointed the auditors of the Company.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

Report of the directors and abstract of accounts for the half-year ending June 30, 1895, to be submitted to the fourteenth half-yearly general meeting of the shareholders to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, August 13, 1895, at 3 p m.:

Directors: Sir William Bower Forwood, J.P., Ramleh, Blundellsands (chairman); James Barrow, Esq, J.P., 7, Beach Lawn, Waterloo; John Brancker, Esq, J.P., Green Bank, Wavertree; Harold Brocklebank, Esq., 20, Bixteth-street, Liverpool; Richard Hobson, Esq., J.P., 54, Brown's-buildings, Liverpool; Edward Lawrence, Esq., J.P., 5, Fenwick-street, Liverpool; George H. Robertson, Esq., F 24, Exchange-buildings, Liverpool. Engineer and manager: S. B. Cottrell, Esq., M.I.C.E., 31, James-street, Liverpool Secretary: William H. Alexander, Esq., C.A., 24, North John-street, Liverpool.

In presenting the half-yearly statement of capital and revenue accounts to June 30, 1895, the directors have to report that the gross revenue receipts amount to £28,143. 3s. 1d., and the working expenses to £18,653. 18s. 1d. The number of passengers carried since the opening of the railway being as follows:

	Half-year ending Dec. 31, 1893.	Half-year ending June 30, 1894.	Half-year ending Dec. 31, 1894.	Half-year ending June 30, 1895.
First class	260,221	277,653	362,179	400,260
Second class	1,293,840	1,246,975	2,228,224	2,114,462
Workmen (special return tickets)..	921,578	1,336,809	1,050,976	945,338
Total.....	2,475,639	2,861,437	3,641,379	3,460,060

These figures show a continued and satisfactory increase in the traffic. The contracts for the southern extension have been let, and the works will be commenced without delay. In order to meet the necessary expenditure, your directors have decided to offer to the shareholders at par, on application, the unissued portion of the ordinary capital.

Revenue Account.

Receipts from passenger traffic amount to	£27,708	6	1
Miscellaneous receipts	434	17	0
	£28,143	3	1
Less working expenses	18,653	18	1
	£9,489	5	0
Deduct interest on mortgage debenture	2,500	0	0
	£6,989	5	0

DIRECT UNITED STATES CABLE COMPANY.

The ordinary general meeting of the Direct United States Cable Company was held on Tuesday, Sir John Pender occupying the chair.

The **Chairman** said that the depression in the United States had resulted in their being able to pay only 2 per cent., instead of 5 per cent. as in former times. The Company was in a very sound position, and he hoped for a return of their former prosperity. The report was adopted.

THOMAS PARKER, LIMITED.

The report of this Company for the year ending April states that the Company was formed in 1894, but only commenced work as a manufacturing concern about the end of January last. By far the larger portion of the management and working expenses, staff salaries, etc., having been incurred in the development of the business, planning, designing, and erection of the buildings and plant, the preparation of loose tools, patterns, etc, the directors might have charged a very considerable proportion of these expenses to plant, etc., but have preferred to charge them all to a general account, the balance of which is £4,143. The directors propose to transfer £3,000 of this amount to the goodwill and development account, and to treat the balance, £1,143, as preliminary expenses, to be dealt with in future accounts. Many important contracts and orders have been already secured, and the trading prospects for the year are such as to give the directors the fullest satisfaction.

LEIPZIG TRAMWAYS COMPANY, LIMITED.

The directors of the Leipzig Tramways Company, in their report for the financial year ended June 30 last, state that the total receipts for the year were £109,934, compared with £105,449 in the previous year, and the total expenses were £78,779, against £77,048, the profit being £31,155, against £28,401. The cost of working is thus 71·68 per cent. of the receipts, as against 73·07 per cent. in the previous year. Owing to the very long and severe winter the expenses for the maintenance of the permanent way, and for the renewal of horses, have been materially increased, otherwise the working expenses would have again shown a reduction this year, notwithstanding the small increase in the car mileage. In accordance with the resolution passed at the extraordinary general meeting of the shareholders held on April 1 last, the directors have entered into an agreement with the Gesellschaft für Elektrische Unternehmungen for the transfer of the undertaking to a German company with a view to working the tramways by electricity. This agreement, they are informed, has been approved by the municipal authorities of Leipzig, and has now to receive the sanction of the Government. After providing for debenture interest, the interim dividend, and all other charges, there remains a balance of £9,314, out of which the directors have placed £2,000 to the credit of the reserve fund, and now recommend the payment of a dividend of 4½ per cent. for the six months on the ordinary and preference shares, which will make, with the interim dividend paid in February last, a dividend of 7½ per cent. for the year on both preference and ordinary shares. The dividends will absorb £7,110, leaving £204 to be carried forward.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ille-sur-Tet.—La Mairie d'Ille-sur-Tet, Pyrénées-Orientales invites tenders by August 11 for the concession of the electric lighting of the town.

Brighton.—The Corporation invite tenders by August 10 for the supply and erection at the electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping. Specifications can be obtained from the town clerk.

King Cross (Halifax).—Tenders are invited for the electric lighting of the King Cross Constitutional Club. The building can be inspected between 9 a.m. and 5 p.m. on application to the steward. Tenders to be in by 5 p.m. on August 5, addressed to the chairman of the House Committee.

Aylesbury.—Tenders are invited for lighting the public lamps and clock tower within the district for one year from September 1, for the Aylesbury Local Board. The conditions for lighting and all other particulars in connection therewith may be obtained on application to Mr. George Fell, clerk, Aylesbury, to whom tenders must be sent by August 9.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep

Digitized by Google

burning at the same time 2,200 8-c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E. engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Edinburgh.—The Town Council are prepared to receive tenders for the supply of (1) insulated concentric cable for high-pressure alternating current; (2) for transformers. Specifications can be obtained from the resident electrical engineer, 5, Dewar-place, Edinburgh, on payment of a deposit of one guinea, which will be returned on receipt of bona fide tender. Sealed tenders are to be lodged with the town clerk not later than 10 a.m. on Friday, August 9, 1895, endorsed "Tender for Concentric Cable" and "Tender for Transformers."

Leicester.—Tenders are invited by the Gas and Electric Lighting Committee of the Town Council for the manufacture, delivery, and erection of a cast-iron water-tank, to be placed upon a tower at the Aylestone road works. Drawings may be seen and specification and form of tender obtained upon application to Mr. Alfred Colson, M.I.C.E., engineer, Millstone-lane, Leicester, and on payment of £5, which will be returned on receipt of a bona fide tender. Tenders, addressed to Alderman Lennard, chairman, endorsed "Tender for Water-tank," to be delivered by 11 a.m. on August 10.

Romford.—The Romford Urban District Council invite tenders for lighting the public lamps in the town of Romford, as to about 190 of such lamps from sunset to sunrise, during 12 months from September 1. Tenders to include the cost of lighting, cleaning, and repairing, and are to be sent to Mr. Geo. Bailey, clerk, Romford, by 4 p.m on August 6. A contract and (if necessary) a bond with sufficient sureties will have to be entered into and given by the person or persons whose tender may be accepted. Further particulars may be had on application to the surveyor. No special forms of tender.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Wakefield.—The Corporation invite tenders for the supply and erection of the following: Section A—boiler house plant (boilers and fittings, mechanical stokers and engine economiser, feed-pump, injector, etc.); Section B—engine-house plant (steam alternators, condensers, oil filter, fittings, etc, steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tank, etc.); Section C—main switchboard and instruments; Section D—underground work (cables, junction-boxes, culverts, and trenching, etc.); Section E—sub-station fittings (transformers and switchboard, etc.); Section F—arc lamps and posts; Section G—meters; and Section H—overhead crane. Particulars are obtainable from Mr. Robert Hammond, Ormond House, Great Trinity-lane, E.C., on and after August 2 on payment of £2. 2s, which will be returned on receipt of a bona fide tender. Tenders are to be delivered by August 24.

London, W.C.—Tenders are invited for the erection of a laboratory in Clement's-lane, London, W.C., for the Commissioners of H.M Works and Public Buildings. The site can be inspected by appointment with the clerk of works at the Patent Office Extensions, Took's-court, Cursitor-street, E.C., between 2 and 4 p.m. Drawings, specification, and a copy of the conditions and form of contract may be seen on application to Mr. Taylor, 12, Whitehall-place, S.W., between 11 a.m. and 1 p.m. Bills of quantities have been prepared for the use of builders by Messrs. Welch and Atkinson, 10, Lancaster place, Strand, and, together with forms of tender, may be obtained at H.M Office of Works, 12, Whitehall-place, S.W., on payment of £1. 1s. The sums so paid will be returned to those persons who send in tenders in conformity with conditions specified. Tenders are to be delivered before 12 noon on August 7, addressed to the Secretary, H.M. Office of Works, etc., 12, Whitehall-place, London, S.W., and endorsed "Tender for Laboratory."

RESULTS OF TENDERS.

London W.—The following tenders have been received for the electric lighting of St. James' Club (part of). Mr. W. Howard Tasker, M.I.E.E., 12, Pembroke-road, Kensington, W., is the consulting engineer:

Crompton and Co.	£573.	10	0
Clarke and Co.	536	6	0
Drake and Gorham	518	18	0
Moody Bros.	475	5	0
Belshaw and Co. (accepted)	467	14	9
Verity and Sons	432	10	0

Dewsbury.—The following is the list of firms who tendered for the Dewsbury Pioneers Industrial Society's electrical installation:

Electroliers included.

Electrical and Mechanical Supply Company, Leeds	£1,580	0	0
Lowcock, Hill, and Co., Manchester	1,250	0	0
J. A Edmondson, Leeds	1,185	5	1
S. Z. Waring and Son, Manchester	1,075	0	0

Crompton and Co., Limited, London	915	0	0
G. A. Steinthall, Bradford (accepted conditionally)	730	0	0
H. F. Joel and Co., London	952	17	0
Maunsell, Mercier, and Co., Manchester	727	0	0
A. Sykes, Huddersfield	667	10	0

Electroliers not included.

A. Hirst and Son, Dewsbury	777	0	0
Manchester Edison-Swan Company, Limited	743	0	0
Sharp and Kent, London	616	0	0
B. Verity and Son, Manchester	610	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,109.

Rand Central Electric Works, Limited.—The offices have been removed from Warnford-court, E.C., to 120, Bishopsgate-street Within.

City of London Electric Lighting Company, Limited.—Warrants for the interim dividend on the 6 per cent. preference shares have been posted.

Westminster.—It is stated that the annual gas bill of the Houses of Parliament is £3,000, the bill for electric light £1,800, and, in addition to the gas and electric light, the use of oil-lamps costs £1,250.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 28th ult. amounted to £1,197, as compared with £933 in the corresponding week of last year, being an increase of £264.

Hackney.—The Vestry have decided to introduce the electric light in conjunction with a dust destructor. The scheme has been entrusted to Mr. Francis Hastings Medhurst, the consulting electrical engineer.

Folkestone.—A meeting of the Town Council has been held at which Mr. Medhurst's bill for £55. 18s. 1d. for professional services was, on the motion of Mr. Pursey, seconded by Mr. Thompson, referred to a committee.

St. James and Pall Mall Electric Light Company, Limited.—The share transfer books will be closed till August 7, preparatory to the payment of an interim dividend on the ordinary and preference shares for the half-year ending June 30.

Church-Lighting.—The Tayler Smith Electric Company have just been entrusted with the installation of the electric light in St. Mary's, Aldermanbury, E.C. Some 200 lights of varying candle-power will be employed. The work is to be carried out at once.

Venezuela Telephone and Electrical Appliances Company, Limited.—Coupon No. 10 of the 5 per cent. first mortgage debentures, due July 31, will be paid from that date at the Consolidated Bank, Threadneedle street, E.C., or at Messrs. Westendorp and Co.'s bank, Amsterdam.

Light Railways, Tramways, and Cable Transport Syndicate, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to construct, maintain, and work any railways, light railways, roadways, tramways, or cableways in the United Kingdom or elsewhere.

Harrogate.—Mr. Geo. Wilkinson, M.I.E.E., has been appointed to advise on the lighting of the new Montpellier Baths, which are being erected by the Corporation at a cost of £75,000. The current will be obtained from the Corporation electricity works, which Mr. Wilkinson has also in hand.

Bromley (Kent). — At the District Council's last meeting a letter was read asking the Council to assist a syndicate which had been formed to introduce electric lighting in Bromley, the provisional order having lapsed. The letter was referred to the Standing Orders Committee.

Barmouth.—Notice has been received by the Urban District Council that the Barmouth and District Electric Lighting and Power Company intend applying next session for a provisional order for public and private lighting. Mr. Thos. Blackburn, C.E., of Barmouth, is the engineer for the scheme.

Douglas (Isle of Man).—The chairman and directors of the London and North-Western and Lancashire and Yorkshire Railway Companies arrived at Douglas on Monday last by the steamer "Duke of Lancaster," and inspected the Douglas and Laxey Electric Tramway and the Snaefell Mountain Railway.

Digitized by Google

Telegraphy in India.—The Director-General of Telegraphs, says *Indian Engineering*, has been instructed to arrange for the construction of a telegraph line from Bezwada to Ennore before September 1 next, by which time the Royapuram-Ennore section of the Bezwada-Madras Railway should be opened for traffic.

City and South London Railway.—The returns for the week ending July 28 were £827, compared with £858 for the corresponding period of 1894, being a decrease of £31. The total receipts for the half-year 1895 are £3,421, as compared with £3,458 for the corresponding period of 1894, being a decrease of £37.

Automatic Electric Sign Company, Limited.—This Company has been registered, with a capital of £5,000, to enter into two agreements, dated June 15, with G. F. Kenyon, to acquire any patents or inventions capable of being used in connection with the supply of electricity, and to develop and turn to account the same.

Charing Cross and Strand Electricity Supply.—The directors of the Charing Cross and Strand Electricity Supply Corporation, Limited, have declared an interim dividend for the half-year ending June, 1895, at the rate of 4 per cent. per annum on the ordinary share capital of the Corporation (£150,000), and carried forward £2,870.

New Phonophore Telephone Company, Limited.—This Company has been registered, with a capital of £10,000, to enter into an agreement with the Phonophore Company, Limited; to acquire any patents, patent rights, etc., relating to improvements in telegraphic, telephonic, etc., apparatus, and to develop, work, and generally turn to account the same.

Helios Arc Lamps.—We have received from the International Electric Company, 55, Redcross-street, Barbican, E.C., a copy of their new edition of the Helios arc lamp list, which gives details of the construction, use, and management of the same, with numerous illustrations. There is also a list of the electric light supply stations in this country in connection with which these arc lamps are used.

Electric Ozone Syndicate, Limited.—This Company has been registered, with a capital of £12,000, to enter into certain agreements for the acquisition, by purchase or otherwise, of certain patents relating to improved means of generating and dealing with ozone by means of electricity, and to develop and turn to account the same; as mechanical engineers, etc. Registered without articles of association.

Blackpool.—The quarterly meeting of the librarians of the Mersey district was held at Blackpool on Friday last, when representatives from the libraries at Liverpool, Birkenhead, Leigh, Blackburn, Fleetwood, and other places were present. Set papers were dispensed with owing to an accumulation of questions for discussion, these comprising points in the electric lighting of libraries, ventilation, etc.

Poplar.—The District Board of Works have held a meeting, at which a communication was received from the Board of Trade to the effect that in the circumstances referred to by the Board they were prepared to defer the consideration of the question of the revocation of the electric lighting order for a year from the present date. Mr. Bussey: I suppose we will get another year after that. The Clerk (Mr. Wm. Farnfield): I suppose so.

Launch-Lighting.—The anniversary dinner of the Royal Windermere Yacht Club took place at the hotel adjoining the yacht club on Saturday last. A large assembly collected to witness the fireworks got up by the yacht club. Another feature of the illuminations was the electric launch "Lady May," which was most tastefully decorated by means of several 16-c.p. 100-volt lamps, the same being controlled by the lever switch that worked the motor.

Dover.—At the Town Council's last meeting the surveyor reported that the notice of laying electric light mains in Maison Dieu-road, etc., was an extension of the system beyond the original scheme. There would be several transformer chambers put in. He recommended the approval of the application. A plan with the position of the arc lamps in Snargate-street was received from the company and referred to the Pier and Town Wards Lighting Committee.

Fire Brigade Alarms.—At Tuesday's meeting of the London County Council, the Fire Brigade Committee recommended that the seal of the Council be affixed to agreements (in duplicate) with the Post Office in respect of telephonic communication between the Mile End station and the Burdett-road street station, and between the Holborn station and the Strand street station, and to agreements in respect of two fire-alarms in Ancona-road, Islington, and Broughton-road, Fulham, respectively.

St. George's (Hanover-square).—At the last meeting of the Vestry the Joint Vestry Hall Committee presented a report recommending that the Board-room and the offices be fitted with electric light, at a cost of £150 each to the Guardians and Vestry. Mr. Bromwich, while not hostile to the use of the electric light, thought they should wait until they had all the figures before them, and he moved the adjournment of the question for that purpose. After some discussion this was agreed to.

Partnership.—Mr. R. Booth, of 110, Cannon-street, E.C., has taken into partnership Mr. H. W. Ravenshaw, A.M.I.C.E. Mr. Ravenshaw for the past 11 years has been chief of the electrical staff of the firm of Messrs. W. T. Goolden and Co., whose business is now merged with that of Messrs Easton and Anderson, Limited, of Erith, and Mr. Ravenshaw's services have been retained by this firm as consulting electrical engineer. Mr. Ravenshaw has been identified for many years with the transmission of motive power by electricity, and has carried out some of the leading installations as well as central-station and general electric lighting.

Whitechapel.—A meeting of the District Board has been held, at which, upon the question of a notification that an electric lighting company was about to apply for a provisional order to light the Whitechapel district, Mr. Catmur moved: "That it is undesirable that the electric lighting of the district should be in the hands of a private company, and that the notice from the Capital and Counties Electricity Supply Company should be referred to the Streets Committee for consideration and report." This was agreed to.

Alderley Edge.—The monthly meeting of the District Council was held on Monday night, when a letter was read from Mr. S. V. Clirehugh, electrical engineer, Manchester, stating that he had been requested to ask the Alderley Council if they were prepared to dispose of the electric lighting provisional order which had recently been granted to them. After discussion it was decided that the clerk should reply that the Council were prepared to dispose of the order on an adequate payment being made, and on an undertaking being given that the lighting should be carried out in accordance with the views of the Council.

Birkenhead.—A local paper says: "The District Council have before them for consideration a scheme for lighting the place by electricity. A firm of electrical engineers have offered to lay down plant for the purpose which will cost the Council no more than £500 a year, the sum now being paid for gas. The power will be obtained from one of the newly-invented wind motors, which will be erected at Hilbre Point near the red rocks, and the firm are so confident of success that they offer to lay down the plant and give a supply for six months, and if not satisfactory they will remove it at their own cost and make no charge for the supply."

Barry.—The directors of the Barry Railway Company are about to make arrangements whereby the whole of their passenger trains will be lighted by means of electricity. With this object in view a new first and second class coach, specially fitted with electric appliances of the most improved type, was put on the line one evening last week for test purposes, and the new arrangement fulfilled in the most satisfactory degree its requirements. The supply for the coaches will be entirely independent of each other. The experiment having proved admirably successful in every detail, it is expected the whole of the passenger service on the Barry railways will be lighted by means of electricity.

New Mains in London.—The Notting Hill Electric Lighting Company intend to lay mains and to construct street boxes in and across Addison-road and in Bedford-gardens. The House-to-House Electric Light Supply Company will lay high and low tension mains across Richmond-road. The Hampstead Vestry will lay mains in Goldsmith-place, Springfield gardens, Alexandra-road, Avenue-road, Upper Avenue-road, Kidderpore-avenue, North End-road, alongside Hampstead Heath, Heath-street, Finchley-road, Hampstead-hill-gardens and Belsize-park-gardens. They will also construct a sub-station at the corner of Alexandra-road and Abbey-road. The London County Council have approved of these works.

Copper.—Under Wednesday's date, Messrs. Lewis Lazarus and Sons report: Copper was again very strong in New York and purchases of American copper were made here for reshipment. Meanwhile the advance here moves slowly, to-day's gain being only 5s. per ton. On first 'Change 800 tons were taken at £45. 7s. 6d. and 8s 9d. cash; £45. 10s. and 11s. 3d. for late August dates; £45 12 6d. and 13s. 9d. for September; £45. 15s., 17s. 6d., and 16s 3d. three months. Fully 700 tons more were done on second 'Change, prices moving from £45. 10s. to 12s. 6d. for August dates; £45. 16s. 3d. to £46 three months. Closing values £45. 12s. 6d. cash; £46 three months; settlement price £45. 10s.

Lighting Corporation, Limited.—This Company has been registered, with a capital of £250,000, to maintain and uphold any appliances, apparatus, or plant requisite for gas, electric, oil, or any other methods of lighting now in vogue, and to carry on, in all their respective branches, the businesses of manufacturers of and dealers in incandescent lights and other apparatus for increasing the illuminating power of gas, spirits, oil, or other light and heat producing agents, suppliers of light, heat, electricity, and motive power; as electricians, gas engineers, gas workers and fitters, manufacturing, analytical, and general chemists, chemical manufacturers, mechanical engineers, and ironmongers.

Glasgow.—The Electric Lighting Committee of the Town Council have held a meeting, at which it was stated that the gross revenue for the year had been £21,196 11s. 4d., and the gross expenditure, including depreciation, £17,138 18s. 9d., leaving a balance to be carried to profit and loss account of £4 057. 12s. 7d. Out of this the committee have paid £5 000 on interest, loans, and sinking fund, leaving a deficiency of £1,500, which is transferred to the gas account. The committee recommend that the price of the current be continued at 6d. per Board of Trade unit, and they anticipate that, with the increased consumption, next year will be a more prosperous one. They began the year with 208 more customers than last year.

Bradford.—A special meeting of the Gas and Electricity Supply Committee of the Bradford Town Council was held on Monday to appoint, subject to the approval of the Council, a successor to Mr. S. W. Baynes as electrical engineer at the Corporation electricity works. Mr. Baynes sent in his resignation a little while ago in order to take up an appointment in London. The number of applicants for the position which he has resigned was 58, and three of these gentlemen had interviews with the committee on Monday. The result was that Mr. Alfred H. Gibbings, A.I.E.E., who for the past two years has filled the post of electrical engineer

Digitized by Google

to the Hull Corporation, was selected for the appointment at a salary to begin with of £300 a year. Mr. Gibbings is 29 years of age and had experience at Brighton before entering the service of the Hull Corporation.

Devonport.—At the last meeting of the Town Council the town clerk read letters from two electric lighting companies notifying their intention of applying for powers to supply Devonport with electric light. At a subsequent stage of the meeting the Highways and Streets Committee reported that Mr. Paris, representing the London Brush and Provincial Electric Light Company, attended before them, and explained the objects of the company applying to the Board of Trade for a provisional order, and the terms under which they would be prepared to hand over the property to the Corporation in a stated period. The Town Clerk advised the Council to proceed cautiously. It was his opinion that the Council should obtain its own provisional order, and afterwards make arrangements with some electric lighting company. After some discussion Mr. T. W. Martin moved and Mr. Ryder seconded that the matter be referred back to the Streets Committee to report upon. This was agreed to.

Instruments.—Messrs. Evershed and Vignoles, Limited, electrical engineers, Woodfield Works, Harrow-road, W., have purchased from Messrs. Easton, Anderson, and Goolden, Limited, the instrument business founded by Messrs. Goolden and Trotter in 1886. They state that they will endeavour to maintain the reputation established by their predecessors by making careful design, and workmanship of the highest class, essential features of every instrument, from the cheapest gauge to the most costly standard which they produce. The whole of the Evershed patents having passed into their hands, they will continue to make the various instruments associated with that name, including the Richards-Evershed system of electrical ship's telegraphs now being introduced into the Navy and they have therefore retained the services of the whole of the technical staff, who have had many years' experience of this work. No change is contemplated in the general scope of the business, but they will, as occasion offers, take up the manufacture of such electrical and kindred apparatus as may meet the special requirements of the engineering industry.

Islington.—At the last meeting of the Vestry the Vestry Clerk said the Electric Lighting Committee had met that evening, and reported that they had considered the question of the advisability of a public opening of the central electric lighting station, and were of opinion that such an opening would conduce to the success of the electric lighting undertaking in the parish by bringing the attention of the public thereto; and they recommended that a memorial be prepared and presented to his Royal Highness the Prince of Wales, with a view to his performing the opening ceremony in November next. Mr. Lambert moved: "That a petition be presented, under the seal of the Vestry, to his Royal Highness." Mr. Street seconded. The motion was agreed to. On a question of referring accounts to the Finance Committee for payment, Mr. Bryen asked why a sum of £3 had been incurred to make the electrical engineer a member of the electrical section of the London Chamber of Commerce. Mr. Lambert: To enable Mr. Gay to represent us at the Chamber of Commerce. Mr Gay agreed to pay the money himself, but we thought he should not do that. The accounts were passed.

Fulham.—The Electric Lighting Committee of the Vestry have held a special meeting with respect to the proposed installation of the electric light in the parish in connection with a dust destructor. Mr. Threlfal moved that the clerk should be instructed before any further steps were taken in the matter to request the various parishes of London and other places in which the electric light had been installed, whether by their parish authorities or by companies, to furnish the Fulham Vestry with the best information they could upon the number of shops and other places of business within the area of supply and the number taking the light, the number of houses and the number taking the light, with the ratable value of the houses and shops supplied; the length of roads; the system of gas lighting in use, and its cost previous to the introduction of the electric light; and the amount charged to the parish for the lighting by electricity, and the number and kind used. Mr. Threlfal said the lights for St. Pancras cost each £46 per annum, while the cost of gas was £3. One electric light was equal to 4½ gas lamps, so that they had a cost of £46 compared to £13. 10s. in electricity and gas. The whole of the electric lighting cost £4,000, or nearly as much as Fulham paid for the whole of the gas for the parish. Mr. Comben said that out of 18 municipalities now using electricity 16 were making a profit—10 of them as much as 3½ per cent—and of 28 private companies only two or three showed a loss. The motion of Mr. Threlfal was carried.

Toxteth.—On Saturday, at the invitation of the Urban District Council of Toxteth Park, a large number of gentlemen interested in sanitation inspected the new destructor works and depôt constructed by that Council at Richmond Lodge, Smithdown-lane. There are six cells or furnaces erected back to back, with a main flue to carry off the gases placed between, on the Fryer principle, as improved by the manufacturers, Messrs. Manlove, Alliott, and Fryer. The gases pass from the main flue through a Jones cremator, which is maintained at a temperature of over 1,000 F., which is found to be sufficient to destroy all noxious gases produced in the cremation of house refuse. From the cremator the gases pass through a large multitubular boiler, 12ft. in length and 7ft. in diameter, or through a by-pass flue, and then through the screen chamber to the chimney, which has a height of 185ft. 6in from the top of the concrete foundations, and is 5ft. 6in. in diameter. The steam is used for driving a small engine which works the firebars to the cells and supplies steam for the engine at the depôt, besides an engine which drives a dynamo providing electric light for the destructor works and the approach roads. The electrical installation has been erected to the specification and under the supervision of Mr. W. G. P. Macmuldrow, electrical inspector to the Corporation of Liverpool. The Council have executed with their own staff work to the extent of £1,170 5s 9d. out of a total expenditure of £7.888 8s. 5d. in excavating site, making embanked approaches, constructing roads, sewers, and all concrete work in foundations and floors The remainder of the work was carried out by various contractors as follows: retaining walls, Messrs. Kelly Bros., Walton, £290. 7s.; chimney, Messrs. Holden and Myles, Stalybridge, £1.001. 14s; buildings, Mr. John Webster, Wavertree, £1,107. 13s. 3d.; destructor furnaces cremator, boiler, screens, etc., Messrs. Manlove and Co., Nottingham, £4,080. 18s 5d.; and electric installation, £237. 10s.

Liverpool.—A meeting of the Special Lighting Committee of the City Council was held this week at the Municipal Offices. The chairman's report as to the recent negotiations, which have resulted in the purchase by the Corporation of the undertaking of the Liverpool Electric Supply for a sum of about £400,000, was considered and put into its final form. The committee thereupon approved of it, and it will be circulated as soon as it is printed for the information of the Council and of the general public. A special meeting of the City Council has been summoned for Wednesday, September 4, to consider, and if thought expedient to approve of, the intention to make application, and of such application to the Board of Trade by the Mayor, aldermen and citizens of the city of Liverpool, acting by the Council of the city, and being the local authority of the city, for the purposes of the Electric Lighting Acts, 1882 and 1888, for a provisional order to supply electricity, for public and private purposes, under the provisions of the Acts, within the area of the city of Liverpool, as the same may exist at the time of granting the said order.—The Howe Electrical Engineering Company, of Liverpool, have lately carried out some extensive work in and near Liverpool, having had a large installation at Thornton Hall, near Neston, Cheshire, and several small installations. They have just installed complete at the Paddington Theatre of Varieties, Edge-hill, in that city, an engine, dynamo, 580 16-c.p. lamps, and six arc lamps. The engine is driven by gas, and is one of Messrs. Crossley Bros.' latest type, having only one flywheel, weighing nearly four tons, with a third bearing. The dynamo was made by Messrs. Laurence, Scott, and Co., Limited, Norwich, for whom the Howe Electrical Engineering Company are sole agents in Liverpool and district, and is a machine capable of working at full load at 240 amperes at 110 volts. The switchboard and distribution boards have been specially designed by the Howe Electrical Engineering Company to meet the requirements of the theatre, and it is possible to change the colour and control the lights on the battens, flies, footlights, stage, and in the house from any section, and to graduate them from full intensity down to absolute extinction.

Bristol.—One of the smartest things in the way of rapid tramway laying ever done in this country, says a Bristol paper, has been the reconstruction of the line of rails from the end of West-street to St. George's Church (the present terminus) by the Bristol Tramway Company, in connection with their four miles of route for the electric tram service between Bristol and Kingswood. The distance between the end of West street and St. George is two miles, but with the large portion of double line the actual run of single line laid has been three miles, and this work has been done in six weeks, or at the rate of a mile a fortnight. The company, after abandoning their first intention of adapting the old line with its T rails and chairs, which might not have been heavy enough to wear well under the strain of the weight of the electric cars, determined about two months ago to lay down a new line with girder rails, and a heavier form of construction, uniform with the new section in course of construction from St. George to Kingswood. They were, however, at once faced with the difficulty of accomplishing this additional work in time to open the whole line at the end of August. At this stage they sought the assistance of Mr. J. C. Robinson, C.E., upon whose report they had already acted in connection with the whole electrical scheme. Mr. Robinson, who has had considerable experience in work of this kind in America, advised that the construction could be carried out, and completed, if necessary even before the completion of the Kingswood extension and the piece of line in Old Market-street, which had been contracted for in November last, if they would give him a free hand. As this section was practically the same number of lineal yards as the Kingswood extension and the Old Market-street line, the company scarcely hoped for such a result, but relying on Mr. Robinson's advice and assistance they determined to do the work themselves and they placed it in his hands. Cordially co-operating with him was Mr. C. Challenger, the traffic manager, who heartily entered upon the work with his old chief, well knowing that a record had to be broken. The organisation of the labour gangs was perfect. Hundreds of men were thrown upon the work, the old line was rapidly removed and a new line with additional doubling and complicated work in connection with the depôt was completed in one month and two weeks from the date of breaking ground; and on Wednesday last week Mr. Robinson was able to report to the directors that the work was completed within the time he had named. The directors were so pleased at this remarkable smartness that they voted £100 for distribution amongst the foremen of the gangs and others engaged in the work as an acknowledgment of the way in which they had stuck to their posts night and day, and the smartness with which everything had gone in the face of the

Digitized by Google

great traffic difficulties in such busy thoroughfares as West-street and Lawrence-hill. The company were so gratified that they only regretted the dispersion of a construction staff which had carried out this smart work in such a satisfactory manner, not only as to time, but with regard to efficiency and greatly reduced cost.

St. Pancras.—The Finance Committee of the London County Council on Tuesday reported that they had considered an application from the St. Pancras Vestry for a further loan of £75,000 for electric lighting. The report continued: "The Vestry, as will be in the recollection of the Council, has already established an electric lighting station in Stanhope-street, has laid mains in various streets, and has built battery sub-stations in High-street, Camden Town, and in Regent's Park-road. On these various works the Council has already advanced or sanctioned loans to the extent of £107,700, and the Vestry finding the demand for electricity is increasing beyond the capacity of the Stanhope-street station, and also to assist in disposing of the parish refuse, now propose to construct a combined electric lighting station and refuse destructor, for which the present loan is required. The Vestry has acquired certain premises in King's-road, Camden Town, for a central lighting station for £8,592. 1s. 10d., and Bangor Wharf, in Georgiana-street in connection with the collection, removal and disposal of house and street refuse (to be used in connection with the electric station) for £9,924 The buildings and works are estimated to cost £27,201, and contracts have been entered into for about £25,000 of this amount. The cost of the necessary engines, dynamos, boilers, switchboards, mains, etc., is estimated at £35,569. in respect of which contracts have already been entered into for £32,092. 10s. 3d. In addition to the electric lighting machinery referred to there are an engine and boiler, two mortar mills, stonebreaker, fans, and other appliances intended for use with the refuse destructor, in respect of which contracts have been taken for £1.100, making with professional and other charges a total of £34 760. 10s. 3d. The Vestry asks that the whole cost may be treated as a loan for electric lighting purposes, and spread over 42 years, but we are of opinion that the cost in connection with the removal and disposal of the street and house refuse must be treated separately, and regard had to the life of that part of the outlay. As the Vestry does not require to take up the whole of the £75,000 at once, we consider that the loan should be limited to the amount at present required—viz. £56,100—and made subject to a restriction as to further borrowing to supply any necessary replacement of plant and machinery until the amount raised has been paid off, any plant requiring to be renewed in the interim being defrayed out of a sinking fund for renewals, or from maintenance account. We accordingly recommend: (*a*) That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of St. Pancras for a loan of £75,000 towards defraying the cost of purchasing the necessary site for and carrying out an electric light installation, and erecting the requisite buildings and plant, and providing and laying the necessary mains in the parish, and also in providing a wharf and land, plant, buildings, and machinery in connection with the collection, removal, and disposal of the house and street refuse of the parish, be granted to the extent of £30.000 for electric lighting purposes, on condition that the loan be taken up at once, interest being charged thereon at the rate of £2. 17s. 6d. per cent. per annum calculated quarterly, and with the principal being repaid by such equal half-yearly payments of principal and interest combined as will repay the amount borrowed within a period of 42 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the Consolidated Loans Fund. (*b*) That it be notified to the Vestry of St Pancras that as they had elected to spread the whole of the initial cost of the electric light installation over 42 years, the Council will decline to give its sanction to the raising of any loan to replace plant and machinery which may be necessary during the currency of the loan, and will expect the Vestry to provide for all renewals required during that period out of a sinking fund to be provided, or from maintenance account. (*c*) That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of St. Pancras for such portions of the above-mentioned loan of £75,000 as relate to the collection, removal, and disposal of the house and street refuse of the parish, be granted to the extent of £26,100 for purchasing the premises, and providing the necessary buildings, plant, and machinery in connection with the collection and disposal of the house and street refuse of the parish, on condition that the loan be taken up at once, interest being charged thereon at the rate of £2. 17s. 6d. per cent. per annum, calculated quarterly, and the principal being repaid by such equal half yearly payments of principal and interest combined as will repay the amount borrowed as to £10,500 within a period of 54 years, as to £9.000 in 30 years, as to £5 400 in 15 years, and as to £1,200 in 12 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the Consolidated Loans Fund. To enable this loan to be completed during the recess, it is necessary that the Council should seal an order sanctioning the borrowing. We have added the amount to the list of the proposed payments, and recommend that the seal of the Council be affixed to the formal orders."—The Electricity Committee of the Vestry have declined to give leave to the London Hydraulic Power Company to lay mains for the service of Messrs. Saunders's premises, 15, Charlotte-street, W., to extend along Tottenham Court-road, Windmill-street, and across Charlotte-street. The reason of the refusal is asserted to be the objection on the part of the committee to the possibility of the company being a rival which should supply motor power so that business premises could supply their own electricity.

Electric Lighting Loan.—The Finance Committee of the London County Council on Tuesday reported: "We have again had under consideration the application of the Vestry of Islington for a loan of £51,000 for the purposes of electric lighting. On January 22 last we recommended the Council to sanction a loan of £18,000 towards the cost of erecting a central station at Eden-grove, Holloway repayable in 50 years, and of £33,000 to provide the necessary plant and machinery, mains and pipes, repayable in 20 years The consideration of the matter was adjourned by the Council from January 22 to January 29, when the recommendation was withdrawn on the implied understanding that a further representation should be made to the Treasury with a view to obtaining an alteration in the periods to be allowed for repayment of loans for the initial cost of electric lighting installations. Our further correspondence with the Treasury was presented to the Council on May 7, the effect of it being that as an alternate method of repayment the Treasury was prepared to approve of an all-round period of 42 years for the entire cost, with a restriction as to further borrowing for replacement until the amount raised had been paid off; any plant requiring to be renewed in the interim being paid for out of a sinking fund for renewals or from maintenance account The Vestry of Islington having been informed of the Treasury decision and of our willingness to recommend the Council to sanction the borrowing of the £51,000 on those terms, either for 42 years for the whole amount, or divided (as above mentioned) for 50 and 20 years, the Vestry replied that they were not prepared to accept the terms offered, and they asked the Council to sanction the borrowing unconditionally of the sum required, the loan to be repaid as provided by Section 190 of the Metropolis Management Act, 1855. This section enacts that for the purpose of providing a fund for paying off mortgages granted under the Act, the Board or Vestry granting such mortgage shall once in every year set aside out of the moneys or rates charged thereby such sum as they think proper, being not less than £2 per cent. on the amount of the principal moneys secured thereby, and the sum so from time to time set aside and all other moneys applied by the Board or Vestry in augmentation of the said fund, is to be applied in paying off the loan, or investing at compound interest until the whole of the principal can be discharged. In making this request it did not appear to us that the Vestry had sufficiently recognised the fact that it is the duty of the Council, not only to see that loans are required for purposes authorised by statute, but to safeguard the interest of future ratepayers by not allowing any burthen of debt to be placed on them which should be borne by the present occupiers; and, moreover, that it has always been the custom to restrict the period of loans to the life of the works to be executed, except that, as previously stated, by arrangement with the Treasury an exception has now been made in the case of electric lighting works for the whole initial cost to be included in one period of 42 years, subject to the special condition above stated. Reporting on a similar application from the Vestry of St. Pancras on May 7, we stated that we considered the condition was a fair one and one which the Council should accept, and the Vestry of St. Pancras also consenting, the loan was concluded on that basis In offering the Vestry of Islington the same terms we considered that we had gone as far as the Council could reasonably be asked to go in facilitating the borrowing of the money, and that we could not advise the Council to give an unconditional sanction to the Vestry borrowing the £51,000. The Vestry has since reconsidered the matter and now asks the Council to sanction the borrowing of the £51,000 and also to lend the money at £2 17s. 6d. per cent, the loan to be repayable in 42 years on the annuity system. This request may now be complied with, subject to a restriction as to further borrowing to supply any necessary replacement of plant and machinery until the amount raised has been paid off, any plant requiring to be renewed in the interim being defrayed out of a sinking fund for renewals, or from maintenance account. We recommend: (*a*) That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of Islington for a loan of £51,000 towards defraying the cost of an electric light installation in that parish be granted on condition that the loan be taken up at once, interest being charged thereon at the rate of £2. 17s. 6d. per cent. per annum, calculated quarterly, and with the principal being repaid by such equal half-yearly payments of principal and interest combined as will repay the amount borrowed within a period of 42 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the Consolidated Loans Fund. (*b*) That it be notified to the Vestry of Islington that as they have elected to spread the whole of the initial cost of the electric light installation over 42 years, the Council will decline to give its sanction to replace any of the plant and machinery which may be necessary during the currency of the loan, and will expect the Vestry to provide for all renewals required during that period out of a sinking fund to be provided or from maintenance account. As the Vestry is anxious to complete the loan, it is necessary that the Council should seal an order sanctioning the borrowing and draw a cheque for the amount of the loan. We have accordingly included the same in the supplementary weekly cash paper, and also the amount required

Digitized by Google

for the stamp duty on the mortgage, and recommend that the seal of the Council be affixed to the formal order."

PROVISIONAL PATENTS, 1895.

JULY 22.

13934. **Improvements in the method of generating electricity for lighting or motive power.** Frederick Gray, 2, Southwood-lane, Highgate, London.

13956. **Improvements in trolley systems of electric propulsion and in apparatus therefor.** Anthony George New, 55, Chancery-lane, London.

13957. **Improvements in trolley systems of electric propulsion and apparatus therefor.** Anthony George New, 55, Chancery-lane, London.

13958. **Improvements in trolley systems of electric propulsion and in apparatus therefor.** Anthony George New, 55, Chancery-lane, London.

13961. **Improved connector for the rails of electric tramways and railways.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (The Compagnie de l'Industrie Electrique, Switzerland)

JULY 23.

13978. **Improvements in the method of and means for stopping electrically-propelled cars.** Arthur Knox Bonta, 70, Market-street, Manchester. (Complete specification)

14014. **An improved electric switch.** Herbert Sefton Jones, of the firm of W. P. Thompson and Co.. 31, High Holborn, London. (Henry Stuebner, Henry T. Paiste, and Warren G. Miller, United States.)

14019. **Improvements in or connected with apparatus for electrically lighting miners' safety lamps.** William Ackroyd and William Best, 33, Chancery-lane, London.

14021. **Improvements in and relating to phonographs and the like.** Edwin Smith, Wallace Lodge, Upper Tooting, London.

14023. **Improvements in writing telegraphs.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London. (Thomas Ewing, jun., United States.) (Complete specification.)

14033. **Improvements in galvanometers.** George Keith Buller Elphinstone, of the firm of Elliott Bros.. 101, St. Martin's-lane, London. (Henry Rowland, United States.)

14049. **Improvements in electric arc lamps.** Daniel Higham, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14051. **A method and apparatus for electrically transmitting writings or drawings.** Bennett Pell, 28 Southampton-buildings, Chancery-lane, London.

14066. **Improvements in winding armatures for dynamos and electromotors, specially applicable to alternators and alternate-current motors.** The Hon. Charles Algernon Parsons, 18, Southampton-buildings, Chancery-lane, London.

JULY 24.

14095. **Improvments in electric battery cells and in the method of applying same.** Bris Doyle, 43, Kennington Park road, London.

14113. **Improvements in the electrolysis of alkaline chlorides.** Alfred Roland Davis, 4, South-street, Finsbury, London.

14114. **Electrical apparatus having movements determined by variations of the electrical resistance of bismuth in a magnetic field.** Johannes Hessberger, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14134. **Improvements in rapid telegraphic transmission on cable lines.** Charles Langdon-Davies, 24, Southampton-buildings. Chancery-lane, London.

JULY 25.

14142. **Improvements in apparatus for the recovery of gold by electrolysis from the sea.** Matthew William Wallbank Mackie, 77, Turnmill-street, London.

14147. **Improvements in electric and other railways and in vehicles therefor.** Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol.

14158. **Improvements in and relating to primary batteries.** Walter Rowbotham, 47, Vittoria-street, Birmingham.

14160. **Improvements in conduits for electric wiring.** Edward William Lancaster, 52, Bristol-road, Edgbaston, Birmingham.

14203. **Improvements in electric switches or parts for making and breaking circuits in electric machinery.** William A'Court Granville Birkin, 1, Queen Victoria-street, London.

JULY 26.

14233. **Process of making acid-proof vessels and electric insulators.** Edward Whitworth and Bris Doyle, 43, Kennington Park-road, London.

14246. **Improvements in alternating-current electric motors.** George Edensor Dorman, The Hawthorns, Newport-road, Stafford,

14257. **Improvements in or connected with the arrangement of conductors for electrically-operated agricultural implements.** Hugo Schimpff, 4, South-street, Finsbury, London.

14267. **Improvements in dynamo-electric machines.** George Frederick Dieckmann, 45, Southampton-buildings, Chancery-lane, London.

14275. **Improvements in and connected with junction-boxes for electric mains.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

JULY 27.

14313. **Improvements in the manufacture of carbon plates, cylinders, and cells for electrical purposes.** Robert Henelade Courtenay, 23, Broad Hinton-road, Clapham, London.

14337 **An improved method of and means for working electric fire-alarms.** Johannes Andreas Bakker, 191, Fleet-street, London. (Complete specification.)

14342 **An improved electrolysing apparatus.** Jules Kolb and Alexandre Daniel Arnold Lambert, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

16046. **Electrolytic decomposition of alkaline salts.** Castner. (Third edition.)

1894.

15985. **Arc lamps.** Akester and Price.

16599. **Regulating electric currents.** Miller.

16857. **Telegraphy.** Delany.

1895.

6681. **Electric switches.** Cronin.

8011. **Electric battery plates.** Hübener.

9513. **Incandescent electric lamps.** Sheppard.

9703. **Electrically transmitting power to vehicles, etc.** Porter.

9806. **Electrolytical apparatus.** Comboul.

10587. **Electric heaters.** Reed.

10930. **Electrolysing chloride solutions.** Hermite and others.

NOTES.

Electric Lighting in Japan.—Mr. Troup, the British Consul at Yokohama, suggests that it would be well to the interest of those who supply electric lighting plant to have expert agents in Japan with detailed specifications at hand when enquiry is made.

Hardly Fair.—The Prague City Council have decided, upon the ground that "no foreign money should be invested in Prague," to reject the whole five tenders for the construction of an electric tramway system in the town, and, in conjunction with the various suburban authorities, to build and work the lines themselves.

The Wail of the Gasman.—Colonel W. T. Makins, who presided at the half-yearly general meeting of the Gaslight and Coke Company the other day, was sad at heart on account of the Thames Embankment. He expressed the hope that the London County Council would experiment with incandescent gas burners on the embankment before deciding on the electric light.

Telephony in Sweden.—Sweden's State telephone is soon to be connected with the State telegraph. Instead of addresses the telephone numbers will be used, the telegraph clerk looking up the address. Messages may be telephoned to the telegraph office and telephoned back, thus dispensing with the greater number of the messenger boys, as in Sweden nearly everyone uses the telephone.

Extraordinary Natural History.—"Prof. Forbes, like most electricians, knows how to crow; but at least, unlike the majority of his professional brethren, he has laid his egg first." So says the *Journal of Gas Lighting, Water Supply, etc.* It will be news to most of our readers that a cock—which is the bird that crows—is capable of laying eggs. Possibly, however, in the gas world the hens go in for crowing.

An Electric Flag.—It is stated that an electrical novelty in the shape of a standard intended for night use has just been delivered from the Kiel dockyard to the German Imperial yacht "Hohenzollern." The flag is four metres square, and the design is traced in coloured electric lamps, which are lighted by a wire from the deck. An experimental illumination proved very successful, and gave the utmost satisfaction to the spectators.

Glasgow Harbour Tunnel.—In our issue of the 12th ult. (page 36), in a description of the Glasgow Harbour tunnel, we stated that the whole of the mechanical work was under the superintendence of Mr. D. H. Morton. This gentleman wishes to state that he was not responsible for the elevators, the credit of the very successful working of which is due to the American Elevator Company, who were entirely responsible for the designing and execution of the work.

The Trans-African Telegraph.—A telegram from Cape Town, dated 2nd inst., states that the Hon. Cecil Rhodes, in reply to a question in the House of Assembly on that day, stated that the proposed trans-continental cable from Cape Colony to Egypt would be eventually built, provided the Imperial Government recognised the obligations with respect to the Soudan, and rendered the work of construction possible by clearing the country of the Madhi and his followers.

Electric Lighting in Austrian Mines and Metallurgical Establishments continues to make steady progress. The State silver smelting works at Pribram are already equipped with it. Then, in the course of the present year, the group of mines to which the Marien, Franz Josef, and Adalberti pits belong is to be electrically lighted, and the illuminant is also to be introduced in the Anna and Prokopi mines at Birkenberg. The installations will be carried out by a local firm.

The First Electric Tramway in Berlin will be opened during this month in the northern portion of the city. The line, which has been built by Messrs. Siemens and Halske, connects the Gesundbrunnen with Pankow. Current is supplied through overhead wires. At every important street crossing, and at distances of about 300 yards, stopping-places are erected. The tramcars will run about every 10 minutes at a maximum speed of 16 English miles an hour. The fare for the whole distance will be 10 pfennige.

The Metric System.—The report of the Committee on Weights and Measures, advocating the adoption of the metric system in Great Britain, has been reinforced, says the *Pall Mall Gazette*, by a proposal which the French delegates to the Geographical Congress were commissioned to place before the Government here. This is, that if the British Government will make the metric system obligatory throughout the Empire, the French Government, in return, will abolish the Paris meridian of longitude and accept that of Greenwich.

Institution of Electrical Engineers.—We are in receipt of No. 118, vol. xxiv., of the *Proceedings* of the Institution. It contains the papers on "A Magnetic Tester for Measuring Hysteresis in Sheet Iron," by Prof. Ewing, and "The Recent Development of the Single-Acting High-Speed Engine for Central-Station Work," by Mr. Mark Robinson, with discussions on same; description of Mr. Joseph Edmondson's "Zero-Torque Electricity Meter"; and "Daily Insulation Testing of Telegraph Lines," by Mr. W. H. Preece.

Parisian Police Boxes.—The Paris correspondent of the *Times* states that the prefect of police has ordered the establishment of 70 "postes vigie" in various parts of Paris. These will consist of kiosks, in which there will always be by day a policeman to give information or help, and at night a second policeman outside to watch the neighbourhood. Each kiosk will eventually be connected by telephone or telegraph with the nearest police station. The officers are to keep a register of the applications made to them. This is likely to be trivial enough for contemporaries, but may be interesting 100 years hence.

Light Railways.—Some interesting reports from British representatives abroad on the subject of light railways have just been issued. Their publication has been delayed owing to the despatches having been placed, in manuscript, at the disposal of the committee of the conference convened by the Board of Trade to consider the question of light railways and tramways. In Belgium there are 75 such lines extending over 836 miles. Of these, six belong to private companies and the remainder to the National Society of Local Railways. Dividends have been steadily increasing. Agricultural products have certainly been benefited by the establishment of light railways, the most remarkable instance being the culture of beetroot, which has received a great impetus, and has, in turn, given rise to the establishment of a large number of sugar factories. In Prussia the light railways, or "Kleinbahnen," number 37, with a total mileage of about 480 miles. Of these the German Government says: "In general the light railways appear to be well adapted to the development and improvement of agriculture and forestry and their accessories, particularly to opening up new markets and facilitating the carriage to and fro of manure and raw produce over a considerable area of country."

The Telephone in Russia.—Russian telephones are divided into three classes—those belonging to and worked by the State; those appertaining to private and public companies under a contract with the State; and those erected by municipal authorities, railway companies, and private persons for their own use. In 1894, there were in operation 34 State telephone systems, with 43 exchanges. In that year public telephone lines were laid in Tomsk, Tjumen Jaroslav, Smolensk, Chernigov, Jalta, and Gatschina. The number of subscribers was 9,398; the lines were 2,582 versts in length. There were 11 telephone systems of the second class mentioned, with 8,000 subscribers and 1,152 versts of lines; while the number of private telephones is stated to be "very large." In January of the present year, State telephone lines were inaugurated at Ekaterinoslav and Feodosia, and others are in course of installation, or are projected, at Samara, Yambov, Poty, Batoum, Novorrossijsk, Berdyansk, Jekaterinoslav. From January, 1895, the tax on municipal telephones has been reduced by 25 per cent. in order to encourage the development of the use of the telephone in the Tsar's dominions.

Indirect Electrolysis.—M. Andreoli has described in *Le Génie Civil* an experiment on indirect electrolysis. Taking a cell divided into three compartments by porous diaphragms, a solution of any salt is placed in the central compartment, whilst the two electrodes are placed in the side compartments immersed in similar or different electrolytes. The decomposition of these latter is, on the current being passed, effected as if the central compartment did not exist, the solution in it being unaffected. In this form the experiment is an old one, but M. Andreoli finds that if a plate or series of plates is placed in the solution in the central compartment, reactions occur which can only be attributed to an indirect or secondary electrolysis. If, for example, the two outer compartments are filled with a solution of common salt, and the central one with a solution of cyanide of gold. Let the anode in the one compartment be of carbon, and the cathode in the other of iron. On passing a current under these conditions chlorine is evolved at the carbon electrode, and caustic soda produced at the other, the cyanide solution being, as aforesaid, unaffected. If, however, whilst the current is passing, a series of metal plates are immersed in the cyanide solution, the gold is deposited on them, though neither chlorine nor soda appears to pass into the central compartment.

Personal.—The Queen on Saturday last held at Osborne a private investiture of the Orders of the Bath, the Star of India, St. Michael and St. George, and the Indian Empire. Mr. William Robert Brooke (late Director-General of Telegraphs in India) was introduced into the presence of the Sovereign, received the honour of knighthood, and was invested by her Majesty with the insignia of the Second Class of the Order of the Indian Empire.—In the course of an article on Lord Kelvin in the *Pall Mall Magazine*, the writer says that he has an extraordinary capacity for turning from one task to another, as if he found inspiration in the change. And yet all his work is elaborate, painstaking to the last degree. If, as they say, genius is the capacity for taking pains, then Lord Kelvin is one of the greatest of this or any age. The other day he delivered a presidential address before the Royal Society, and in it he made use of this expression: "Tribulation, not undisturbed progress, gives life and soul, and leads to success where success can be reached, in the struggle for natural knowledge." It has been said that Lord Kelvin's career has been one of steady progress in the lines of success. So it has, as we may see if we survey the achievements of his half-century of untiring toil. But no one knows except the man himself what tribulation, what disappointments, what long exercise of patience, have preceded the many important discoveries with which his name is associated. He is an indefatigable worker. Investigation must needs be accompanied by unbreakable precision, and this quality Lord Kelvin has to an astonishing degree.

Municipal v. Private Enterprise.—Mr. W. O. Rooper, of Stafford, writes to a local paper as follows: "An impression has arisen in the minds of the inhabitants of Stafford that the Corporation officials are the only persons competent to put up electric light installations taking their current from the public supply mains. In canvassing for work, one is invariably met with the reply, 'Oh, as the Corporation is supplying the current, they will have to test the work, and they may not be satisfied with other firms installations.' Now, at the request of the Corporation officials, I last year went to considerable expense in providing an electric light show at the gas exhibition. I have been engaged in the business for the last 10 years, and have done work in all parts. I use the very best material and employ the most skilled men, and have never fitted up an installation that would not stand the proper tests. Now, when there is a chance of work in the town where I have been a ratepayer for so long, I find it nearly impossible to get employment, owing to the action of our municipal authorities. What is there about the business that makes it necessary for the Stafford Town Council to do it themselves when nearly all other councils in the country leave it to private firms? Why should they not as reasonably become purveyors of meat, bread, coal, or any other commodity? At any rate, if they will do their best to stifle private enterprise, let them do it fairly and squarely, and give up suggesting that they are the only people able to carry out electric work satisfactorily." Mr. Rooper is, however, under a misapprehension in thinking that Stafford is the only town where the municipality undertakes installation work. His grievance is one which exists elsewhere also.

Technical Education.—The following letter has been addressed to the clerks of county councils and to the secretaries of the other bodies enumerated: "Society of Arts, Adelphi, London, W.C., July, 1895.—Dear Sir,—At a largely attended conference on technical education, held at the invitation of this society on June 20 last, the following resolution was passed: 'That, in the opinion of this meeting, it is desirable that provision should be made for examination and inspection in the subjects of instruction undertaken by technical instruction committees, but not at present included in the schemes of the Science and Art Department, the City and Guilds of London Institute, and the Society of Arts, and that, with the object of giving effect to the same, this conference recommends that a representative committee be appointed to draw up a report and prepare recommendations upon the whole subject.' The council of the Society of Arts, desiring to carry into effect the wishes of the conference, have determined to invite the following bodies to nominate representatives on such a committee, which it is proposed to complete by the addition of members of the society's council: the county councils and county borough councils, the City and Guilds of London Institute, the Royal Agricultural Society, the Central Chamber of Agriculture, the National Association for the Promotion of Technical and Secondary Education, the London Chamber of Commerce, the Yorkshire Union of Institutes, the Union of Lancashire and Cheshire Institutes. I am desired to ask whether the technical instruction committee of your county council will be good enough to nominate someone to serve on the committee, which it is proposed shall be summoned to meet at a con-

Digitized by Google

venient date after the summer recess.—Yours faithfully, HENRY TRUEMAN WOOD, secretary."

A Direct Argentine Cable.—The following telegram has been received by the *Times* from its Havana correspondent: "Telegrams received here refer to the difficulty existing between Great Britain and Brazil in connection with Trinidad Island. The island was formally annexed by her Majesty's ship 'Barracouta' in January last, the gunner being appointed governor and the surgeon medical officer. The islet, which is uninhabited and contains no signs of animal life, lies 700 miles to the east and a little to the south of Rio de Janeiro. The party from the 'Barracouta' found the landing difficult. They landed on the western side, where there was much surf and no shelter, and climbing up the precipitous rocks formally read the proclamation of annexation, nailed the British flag on a spar, and buried the proclamation in a bottle at the foot. The exploring party found fresh water in a small valley on the eastern slope and some slight vegetation near the water. In other places there were traces of the stumps of large trees, but no growth. This is the personal report of Lieutenant Ryan, of the 'Barracouta.'" It appears that the situation of this island is such that it forms a convenient landing-place for a direct Argentine cable, free from Brazilian control; this has been talked of for some years back. The decree recently issued by the Brazilian Government directing the purchase of the cables which are laid along the Brazilian coast, has probably brought the direct-cable idea into prominence again. The Paris *Temps* thinks that it is not enough to say that the transatlantic cables between England and South America all touch Pernambuco, that this gives Brazil the upper hand in these matters, that it is, therefore, important to find half-way between Europe and the New World an independent spot for the cables, and that Trinidad Island is just such a spot. Such reasoning might justify the exercise of an existing right, but cannot possibly create such a right.

The Meyer System of Instantaneously Stopping Machinery is described by the author, M. Lucien Meyer, in *L'Electricien* of July 27. His object has been to enable workmen, by means of a series of electric pushes placed at convenient places in the shop, to instantly bring the machinery to a standstill at the first cry of distress uttered by a comrade in danger. His invention consists of a group of apparatus capable of acting together or separately. The first instrument is an obturator placed in a box furnished with a safety valve, and which is traversed by the fluid—steam, gas, compressed air, etc. It consists of a clack-valve articulated on an axis which passes through one of the sides of the box. On the end of the axis is a counterweight lever, on the socket of which is fixed a disc fitted with a stop-notch. The catch engaging this notch is jointed, and forms the armature of an electromagnet. When current is sent into this the mechanism closes the clack-valve, thus cutting off the motive fluid. With the obturator alone, however, an immediate stoppage is not acquired; it is necessary to combine this apparatus with a brake acting upon the flywheel or on the shaft. This brake consists of an eccentric way placed at a short distance from the periphery of the flywheel. At the upper part of this way is a trough or hopper, containing a number of indiarubber cylinders or rollers. The front of the hopper is movable, and, when necessary, the rollers are allowed to drop between the way, which narrows as it descends, and the flywheel, which compresses them, a very powerful and yet easy brakage being thus applied. In experiments made with a 20-h.p. engine, working at a pressure of seven kilogrammes and at 90 revolutions, a stoppage in seven seconds was obtained with the obturator alone, and in two-thirds of a second by the combined action of the obturator and the brake. The third instrument is a speed indicator of special construction.

The Physiology of Death by Electric Shock.—In our last issue (page 130) we quoted an item from the *Lancet* on the mode of death from electric shock. Dr. W. S. Hedley, of Brighton, now writes to that paper as follows on the subject: "An annotation attributes death in electric shock to 'stoppage of the heart.' It is useful to enquire how and why this stoppage occurs. Dr. A. M. Bleile, Ohio, has lately investigated the physiological events which in his opinion lead up to it. Experimenting upon dogs with strong currents of stated strength he finds, on examining the heart immediately after death, that 'the left side is completely relaxed and the right side intensely gorged with blood, as are also the large veins in the immediate vicinity of the heart. . . . . Incisions into the animal are not followed by bleeding, and the arteries are contracted down to a very small calibre.' It was suggested, therefore, 'that the current acted upon the arteries through the nervous centre which controls their diameter.' To test this view dilatation of the arteries and fall of blood pressure was affected by bringing the animal under the influence of nitrite of amyl. Under these circumstances a current of 0·24 ampere at 52 volts for three seconds (ordinarily a fatal dose) did not produce death. The conclusion arrived at is 'that death in electric shock is really due to the fact that the current produces a contraction of the arteries through an influence on the nervous system, and that this constriction of the arteries throws in such a mechanical impediment to the flow of the blood as the heart is unable to overcome, and that where drugs are given to counteract this effect much larger doses of electricity than the ordinary can be borne.' The experimental data on which this opinion is based are given in such detail that the experiments can be repeated and results verified. The paper is a useful contribution to the physiology of death by electric shock. It may be incidentally mentioned, however, that the absolute amount of mechanical energy used, as measured in joules, does not necessarily bear any direct relationship to the physiological effects of an electric current. In other words a weak current for a long time is a very different thing from a strong current for a short time, although in each instance the joules may be the same."

The Science and Art Department.—The following associateships, Royal scholarships, and prizes have been awarded by the Department of Science and Art of the Committee of Council on Education for the session 1894-95 of the Royal College of Science, London, with which is incorporated the Royal School of Mines:—Associateships: Royal College of Science.—Mechanics—1st class, Cecil A. S. Baxter; 2nd class, William F. Nixon and William E. Tubbs. Physics.—1st class, Harold R. Cullen and Robert W. Forsyth; 2nd class, Walter Hewson, William H. Kay, and Joseph H. Vincent. Chemistry.—1st class, Hugh A. M. Borland, John J. Green, Francis C. Harrison, Henry W. Hutchin, William Longshaw, Arthur Nicholls, William F. Swords, and John Thomas; 2nd class, George D. Dunkerley, Reginald W. Ferguson, Herbert G. Hathaway, Andrew More, George Ryce, William Saunders, John Watson, and Frederick P. Wratten. Geology.—1st class, with honours, Thomas Barron; 1st class, James Harrison and Ernest W. Vredenburg; 2nd class, Frank Ackroyd and Henry W. L. M'W. Bourke. Zoology.—1st class, Ernest Stenhouse. Botany.—1st class, William G. Freeman. Royal School of Mines.—Metallurgy—1st class, Leonard

Prescott, and William J. Turner. Mining.—1st class, Heneage W. Finch and Robert W. Pringle; 2nd class, Cecil M. Bryant, Herbert T. Butcher, Thomas L. Dawson, Henry A. Hinton, Edgar S. Jones, Clive S. Long-Innes, Percy W. Lucas, Hugh C. M'Neill, Belfield Marais, and James Morris. Royal Scholarships.—First Year's Royal Scholarships—Ernest Smith, George M. Russell, Frank Fisher, Norton Baron; Second Year's Royal Scholarships—Robert Sowter, Joe Crowther. Medals and Prizes.—Edward Forbes Medal and Prize of books for biology, William G. Freeman; Murchison Medal and Prize of books for geology, John Caspell; Tyndall Prize of books for physics, Part I., William H. White; De la Beche Medal for mining, Robert W. Pringle; Bessemer Medal and Prize of books for metallurgy, John C. Moulden; Frank Hatton Prize of books for chemistry, William Longshaw. Prizes of books given by the Department of Science and Art.—Mechanics, Cecil A. S. Baxter; astronomical physics, Ernest E. L. Dixon, William H. White; practical chemistry, Henry W. Hutchin; mining, Robert W. Pringle; principles of agriculture, William Williams.

Niagara Falls at Work.—Another contribution to correspondence on this subject (see *Electrical Engineer*, August 2, page 128) comes from Mr. Francis Lynde Stetson, who says: "In the issues of the *Times* there have appeared letters from Prof. George Forbes and Lord Kelvin concerning the adoption of the alternating current for the electric power installation at Niagara, and referring to the advice given by them to the directors of the Cataract Construction Company, which did the work. As first vice-president of that company, which sought and gladly received the advice of these two eminent engineers, I feel it due to both of them that the facts should be stated briefly as follows: (1) In January, 1891, Lord Kelvin was chairman, and Prof. Forbes the submitter of a project, to the International Niagara Commission. At the close of that commission everyone condemned and rejected the alternating system, excepting only Prof. Forbes and Messrs. Ganz and Co., of Budapest. (2) In January, 1894, the Niagara directors had adopted the alternating system upon the advice of Prof. Forbes, and with the concurrence of all the expert advisers, including those who had rejected the alternating system in 1891, excepting only Lord Kelvin. Lord Kelvin thereupon sent to us a cable, in which he certainly indicated a strong preference for the continuous current, but intended also (as we are now gratified to learn from him) as recognising that we 'could certainly succeed with the alternate current.' (3) Our decision was thus made because of the prohibitive cost of the continuous-current installation, which in most particulars fully justified the strong preference for it evinced by Lord Kelvin, whose eminent and valuable advice and encouragement we gratefully acknowledge. Except for his early and original support, our plan would have died 'a-borning,' and we thank him for his continuing interest. (4) But the development of our plan must have been long delayed had it not been for the courage and comprehensive knowledge of Prof. Forbes, who alone stood for the absolute commercial advantage of the alternating current, and for his admirable conception of his 5,000-h.p. dynamo, so wonderfully worked out by the Westinghouse Company as to yield 5,315 h.p. in the actual test on June 28, 1895. Prof. Forbes is entitled to the credit, as he must bear the responsibility, of the results of the advice given by him as to the three points stated in his letter of July 25; and we have followed his advice, perhaps not as far as his courage would carry him, yet beyond the former practice of the manufacturers, who now fully occur in the wisdom of his recommendations as adopted. The rotary transformers approved by Prof. Forbes and made by the General Electric Company are worthy of the highest praise for both design and execution. (5) In fine, the extraordinary and gratifying progress in the development of transforming apparatus, and a corresponding reduction of cost, have taken away many, if not all, of the reasons which Lord Kelvin gave against the adoption of Prof. Forbes's original recommendation of the alternating current, which now, as he truly says, 'alone solves the problem well and economically.'"

Lamps Lighted by Electrical Fish.—M. d'Arsonval has been interesting the members of the Académie des Sciences with a description of the experiments which he has recently made in connection with the electric discharge of the torpedo fish. He used several special instruments for recording the phases of the discharge. One of them, which he calls a galvanograph, is a modification of the movable-circuit galvanometer which he devised in 1880 in conjunction with M. Marcel Deprez. It consists essentially of a very light aluminium coil, upon which is wound the circuit traversed by the piscinal current. This coil is fixed to the centre of an indiarubber diaphragm, stretched on a Marey air-drum. This primary drum is connected by an indiarubber tube to a second smaller drum, carrying a short recording needle moving on a smoked cylinder. Another is composed of a silver wire a tenth of a millimetre in diameter and 40cm. or 50cm. long. This wire is stretched horizontally between two rigid supports. In its centre it connects with a second wire held by an indiarubber spring and carrying a needle moving on the recording cylinder. The torpedo is placed on a plate with a metallic bottom, on which is left about ½in. of sea-water to enable the fish to breathe during the experiments. Out of a sheet of tinfoil two electrodes are cut in the shape of the electric organs of the animal, and these two strips are placed on the dorsal surface of these organs and joined by a band of tinfoil 5cm. long. The lower metallic plate constitutes the negative electrode, and the tin strips form the positive electrode of this living electromotor. The electrodes are then united to the various apparatus for measuring or rendering visible the discharge of the organs. To provoke the discharge it is only necessary to pinch with a pair of dissection tweezers the edge of the fins of the fish. As a rule the torpedo contents himself with one discharge of his electrical artillery, but if he be pinched hard he loses his temper and fires rapidly. The curve inscribed by the galvanograph shows that the discharge is not continuous, as M. Marey has asserted that is is; it is composed of from six to ten successive discharges. The back of the fish is always positive and the belly always negative. With torpedoes of about a foot in diameter, which had been kept for about a week in the Laboratoire de Zoologie et Physiologie Maritimes de Concarneau, M. d'Arsonval found that the E.M.F. alternated between eight and seventeen volts, and the intensity between one and seven amperes. He took an incandescent lamp, consuming four volts and one ampere, and connected it to one of the electrical organs. When the fish was tweezed this lamp became brilliantly lighted for an instant. He counsels the experimenter, by the way, to connect the lamp with only one of the organs, and to pinch the fish very lightly, otherwise the lamp will inevitably be destroyed, as happened to him at his initial attempt. He was able to get three lamps—all he had—running. The action of the organs is synergetic and homergetic. Lamps placed on each organ lighted at the same time and showed the same intensity, although on different circuits. The organ, however,

Digitized by Google

rapidly exhausts itself. M. d'Arsonval purposes continuing his experiments, and we shall probably shortly have from him a comparison of the respective electrical powers of the torpedo, the gymnotus or electric eel, and the electric cat—*malapterurus electricus*.

The Falls of Foyers.—The letter of the Duke of Westminster on this subject, to which we referred in our "Notes" of last week, has given rise to a number of letters in the daily papers, in most of which only the æsthetic point of view is taken, and which are not of much interest. The members of the Inverness Field Club visited Foyers and district on Saturday. They were welcomed to the scene of the operations of the British Aluminium Company, Limited, by Dr. Common, F.R.S., resident director, and Mr. Peregrine Birch, engineer. It was seen that the construction of the conduit to convey the water from above the falls to the site of the factory on the western edge of Foyers Bay was being pushed forward by the contractor. For two-thirds of its length the conduit will be in tunnel through the solid rock. It will be about half-a-mile long, and its dimensions are 6ft. by 6ft. About 300 navvies are employed on the work at present, as well as skilled men over them. The conduit runs parallel with the river where it forms the falls, but it is some 20ft. underground, and, so far as could be discerned, the scenery surrounding the falls will not be damaged, although the water will be diverted into the conduit. The overflow of the reservoir will pass into the gorge of the falls. Dr. Common, in the course of an interesting speech, said that all the necessary elements for the cheap production of aluminium have been found in the United Kingdom. Bauxite, the raw material, is extensively found in the mines in the North of Ireland. It will be treated in the company's factory at Larne by a simple chemical process, by which the alumina will be extracted. This alumina will be brought to the factory at Foyers, and there subjected to the electrolytic treatment, by which the pure aluminium will be separated from the oxygen, the latter going away in the air. The pure aluminium will then be collected in the form of ingots and shipped from Foyers to the industrial centres. No solid *débris* of any kind will result from the process under which the company will work. The cost of manufacturing aluminium by steam power would be about £20 per horse-power per ton, whereas at Foyers the cost of manufacture by water power would be £4 or £5 per horse-power per ton. It was that difference that brought the company to Foyers, which they have purchased. He referred to the many uses of aluminium, dwelling upon its great value as an alloy. The damage by their operations to the scenery, Dr. Common assured the visitors, will be absolutely nil. From the utilitarian point of view the opposition to the company, as expressed in the Duke of Westminster's letter to the papers, was absurd. The forces of Nature—such as these falls—should be used for the benefit of mankind, as they were all over the world. Even if there was a little damage to the beauties of Nature, that must be put up with. It would be the object of the company to do as little damage to the surroundings as possible. Nothing would destroy the natural beauty of that glen. The fact of a little water coming down through it or not was a mere detail. The beauty was in the surroundings. Provost Ross asked if there was any truth in the statement that the vegetation would be destroyed. Dr. Common said that, while a good deal of hydrofluoric acid had been given off by the furnaces in the early days of the manufacture of aluminium, it was now absorbed and rendered absolutely innocuous. The remarks of the Duke of Westminster about spoil heaps were also quite baseless. Provost Ross said it was very gratifying to hear those assurances from Dr. Common, and the best thing they could do, in the interests of the Highlands, would be to wish the company all success.

Requires a Grain of Salt.—Dr. Herz has been interviewed by the young man of the *Pall Mall Gazette*, who has calmly swallowed all that was given to him to swallow. His story runs that Dr. Herz expounded the secret of a great invention which he claims to have left behind him. What the details are cannot be revealed, for up to now they are not patented. "But you may believe on my word," said the dying man, noticing a shade of scepticism in his listener, "that what I tell you is the minimum—not the maximum—of what my invention will accomplish. You know that at present, owing to various causes of retardation, the best telegraphic instruments are incapable of transmitting more than 20 words a minute over long submarine cables. By my system it will be possible to transmit upwards of 100,000 words in the same short space of time. You will say that this sounds like a legend—like a wild flight of fancy, but it is not. It is fact already accomplished and capable of application to-morrow to all the instruments in existence. My experiments were carried out years ago before I came to England and fell ill. I had at my disposal all the telegraphic lines of France during the night, and the hours when they were not required by day. Since I have been here I have worked the system out completely in its mathematical and all its other bearings. It only awaits the opinion of a well-known patent lawyer, and then the world may have the details." "Have you calculated the effect of such an invention as you describe?" "I have. It will revolutionise communication throughout the world. My system permits, in the first place, of so reducing the price of communication that it will be possible to cable a message of 50 words for the 2½d. which at present it costs to send a letter. In other words, the maritime postal service will be reduced to the condition of a parcels post, all verbal communication being instantaneous and practically void of cost. In the next place, consider the newspaper of the future. Papers spend very large sums upon private telegrams from different parts of the world in order to be the first in the field with a certain quantity of news which I cannot help regarding as meagre. Think, now, of a paper with direct cable communication through to its own office calling up New York, calling up Melbourne, at times suitable to their longitudes, and receiving direct information at the rate of speed I have indicated. Such a paper would control everything, and I have the power to make that paper, for in granting royalties I shall reserve this right as far as it applies to news. This ideal paper to my mind should have four editions appearing once every six hours. In this way I could collect from places east and west of Greenwich an instantaneous supply of news at the proper time. Our news from one-half of the world at the present rates may be 12 hours behind time because of the alternation of day and night. I should remedy that with my four editions." "And you say that this system with its extraordinary possibilities is ready for application?" "It is ready to-day. It can be applied to the syphon-recorder system, even to the Morse instrument, which you know is in many cases unworkable. This is not all. It will render submarine telephony possible, and it will admit of multiplex telephony—a thing scarcely dreamt of, much less attempted. But the crowning achievement, as I said at the beginning—and I repeat that this no Jules Verne fancy, but an accomplished fact—the crowning achievement is that for 20 words per minute in modern submarine telegraphy my invention will substitute upwards of 100,000."

THE POTENTIOMETER AND ITS USES.

BY ELLIS H. CRAPPER, A.I.E.E.

§ 1. *Introduction.*—The potentiometer, as its name implies and in a restricted sense, is an instrument for measuring *differences of potential*, or E.M.F.'s. The essential part of this instrument consists of a long fine platinoid or German-silver wire stretched over a scale, and when in use the ends of this wire are maintained at a constant difference of potential. Since, however, the three factors—E.M.F., current, and resistance—present in an electric circuit may be expressed in terms of difference of potential, the principle of measuring differences of potential by comparison of the fall of potential along a wire with the E.M.F. of a standard cell may be quite generally applied to the measurement of the three quantities—E.M.F., current, and resistance—with very little preparation and trouble, and with excellent results. When we consider that the potentiometer is both a laboratory and a workshop instrument, that the construction is so simple that anyone may make the instrument at little cost, and that it replaces more expensive apparatus—such as the quadrant electrometer, etc.—and at the same time is easy to manipulate and perfectly reliable, one is surprised that it is not more commonly used. It is because of its almost general application in electrical measurements that we desire to draw the attention of students and electrical engineers generally to the principles applied, and to the construction and methods of using this useful measuring instrument. And here we must mention that we are indebted to Dr. Fleming and Messrs. Crompton and Co., Limited, for the introduction and development of potentiometer methods.

§ 2. It will be well here to point out in connection with

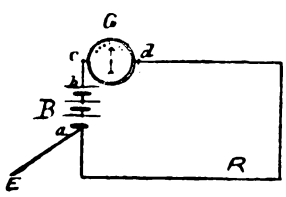

FIG. 1.

Ohm's law, as stated usually—*i.e.*, C = E/R—that E may mean the total E.M.F., or the D.P. between any two points, but in our case we propose to denote E.M.F. by E, and the D.P. between different points by e_1, e_2, e_3, etc., and the corresponding resistances between the points by r_1, r_2, r_3, etc., reserving R for the total resistance of the circuit, thus

$$C = E/R = e_1/r_1 = e_2/r_2 = e_3/r_3 = \frac{e_1+e_2+e_3}{r_1+r_2+r_3} . \quad . \quad (1)$$

From which we see that the E.M.F. distributes itself throughout a simple circuit uniformly, so that the value of C is the same throughout. Probably the distribution of the E.M.F. in a circuit can be better shown graphically than described. For an example we will consider a circuit consisting of a battery, a galvanometer, and a wire, as shown in Fig. 1, in which B is the battery, G the galvanometer, and R the connecting wire. The negative pole of B is earth connected at E.

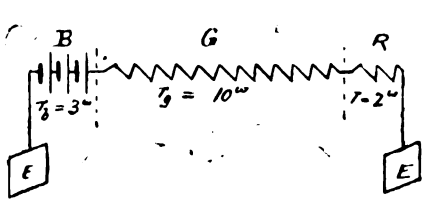

FIG. 2.

If the E.M.F. and resistance, r_b, of the battery be five volts and three ohms respectively, r_g, the resistance of G, 10 ohms, and r, the resistance of R, two ohms, the current traversing the circuit will be

$$C = \frac{5}{3+10+2} = \frac{5}{15} = \tfrac{1}{3} \text{ ampere.}$$

Fig. 2 represents the circuit diagrammatically, the circuit being closed with the earth-plates, E, an arrangement which allows us to fix upon a point of the circuit which may be considered as at zero potential. In Fig. 3 the relation between the resistance and D.P. is shown graphically. Let D.P. be shown as ordinates, and the resistance (by lengths of line) as abscissa. At A the ordinate A Y represents the E.M.F., five volts; at C, the ordinate represents four volts; since if five volts are required to send a current of $\frac{1}{3}$ ampere through the total resistance of 15 ohms, four volts will be required to send the same current through the 12 ohms resistance, in the external part of the circuit. Similarly at D the ordinate represents $\frac{2}{3}$ volt. It will then be found that by drawing a line through the points Y, C^1, D^1, the ends of the ordinates A Y, C C^1, and D D^1, the line is a straight line cutting the abscissa at A^1, which is at zero potential. The line Y C^1 D^1 A^1 thus shows the gradient in the pressure throughout the circuit.

From what has already been said, and from the geometry of the figure, it will be sufficient, in passing, to point out that Y c^1, c^1 d^1, and d^1 A represent differences of potential, and that the pressure required to send the current through any part of the circuit is given by the length of the ordinate subtended by that part of the *line of slope* corresponding to the resistance of that part of the circuit. Again, the line of slope makes an angle θ with the horizontal, from which we see that tan θ = E/R = C, and that the angles C^1 D^1 d, Y C^1 c^1 = θ. Also that $E = e_1 + e_2 + e_3$.

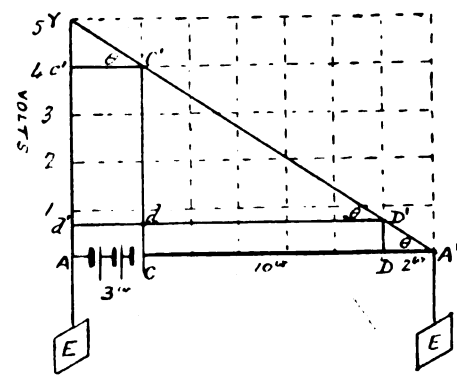

FIG. 3.

We can now deduce some very important relationships between the three factors, E.M.F., C, and R, which will be found useful later on.

1. The fall in potential along a homogeneous conductor is uniform, and directly proportional to the resistance.

2. The D.P. between any two points of a circuit is the same proportion of the E.M.F. (of the circuit), as the resistance between the points is of the total resistance of the circuit, or, algebraically, $e_1/E = r_1/R$, from $E/R = e_1/r_1$.

3. Since $C = E/R = e_1/r_1 = e_2/r_2 = e_3/r_3$ (from equation 1), therefore $E = C R$; $e_1 = C r_1$; $e_2 = C r_2$; $e_3 = C r_3$.

In practice, D.P. is often termed *fall in potential* or *drop in volts*, terms which are in perfect harmony with the results depicted in Fig. 3. The values of the D.P.'s just stated may be given in the general form:

Drop in volts = ohmage × amperage . . (2)

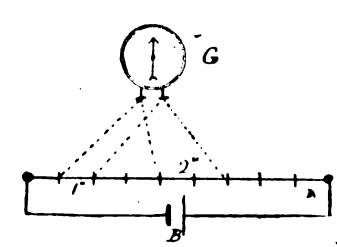

FIG. 4.

where ohmage is the value of the resistance between the two points under consideration.

The following example very clearly illustrates how the above principles may be applied in electrical measurements. A battery of one ohm resistance and E.M.F. E volts is connected to a uniform wire of nine ohms resistance stretched over a scale 9in. long. The D.P. between the ends of the wire will be 9/10 E, and D.P.'s of ·1 E, ·2 E, ·3 E, etc., will

Digitized by Google

exist between points 1in., 2in., and 3in. apart respectively along the wire. If the battery be replaced by another of the same resistance, but of E.M.F. E^1 volts, and it is found that a D.P. between two points in the wire 2in. apart gives the same deflection with a galvanometer—the arrangement is shown in Fig. 4—as the D.P. for 1in. in the former case, then we know that

$$\frac{2}{9}E^1 = \frac{1}{9}E, \text{ or } E = 2E^1.$$

§ 3. *Construction of Potentiometer.*—The details of the construction of this instrument will be apparent from the complete sketch, given in Fig. 5, of one for universal use. Three boxwood scales, A B, C D, E F, each one metre long, and divided into millimetres, are fixed parallel to one another on a stout mahogany board, about 4½ft. long and 9in. wide. H, K, L, and M are pieces of copper ¾in. wide fastened to the board, as shown. The potentiometer wire consists of two fine uniform platinoid or German-silver wires, No. 30 B.W.G., soldered to H, K, and L, and stretched over the scales A B and C D, so that it is two metres long, and is divided into 2,000 parts by the millimetre divisions. At the ends of the scale, E F, there are two terminals, so that a wire may be stretched over the scale (shown as a dotted line) if we wish to determine its specific resistance or compare its conductivity. This will be considered later on. P*p* is a broad copper strip, upon which are soldered six terminals. N is a small switch of five or six contact-pieces, so that in conjunction with P*p* the E.M.F.'s of five or six different cells may be determined or compared without disconnecting or changing the connecting wires, simply by moving the switch arm of N. In the figure, three cells are shown connected up ready for taking measurements. S, S^1, S^2, and S^3 are sliding pieces with copper knife-edges on springs of brass for making contact with the potentiometer wire as desired. The details of these sliding pieces are shown in section at I. and II., from which the construction is apparent. In all cases the small circles indicate terminals. If required, the sliding pieces can be removed with ease, without moving the copper pieces.

§ 4. *Comparison or Determination of E.M.F. or D.P.*—The connections for making these tests are shown in Fig. 5, the additional pieces of apparatus employed not actually forming part of the potentiometer, being a battery of two or three accumulator cells or other reliable cells, if accumulators are not available, a high-resistance reflecting galvanometer, two variable resistances or ordinary resistance boxes, and a Clark standard cell, marked S.C. It will be noticed that the battery is connected to H and L, and that a contant D.P. of two, three, or four volts, as desired, may be maintained at the ends of the potentiometer wire by means of the variable resistance in circuit with the battery. Between the terminal on H and the end terminal at *p* is connected the galvanometer in series with the other variable resistance, whilst the positive pole of the Clark standard cell is connected to the other end terminal at P, thus being in opposition to the battery, and the negative pole is connected to slider S. The cells whose E.M.F.'s are required are connected with the other terminals on P*p* and the switch N, the arm of which is connected to slider S^1, as shown in the figure. As everything depends upon our standard of E.M.F., it is necessary to remember that the E.M.F. of a Clark standard cell varies with changes in temperature, and from a large number of experiments it has been found to have the following values for its E.M.F. at the following temperatures:

Temp. C.	E.M.F. (volts).	Temp. C.	E.M.F. (volts).
0	1·451	16	1·433
5	1·445	17	1·432
10	1·440	18	1·431
12	1·437	19	1·430
14	1·435	20	1·428
15	1·434	25	1·423

Everything being ready, the following is a convenient method of commencing the determinations, and to simplify matters we give the results of an actual experiment in determining the E.M.F. of a Grove's cell, which we shall assume to be represented by C^1 in the figure. It was noticed that the temperature of the room was 15deg. C., and one knife-edge of slider S was set at division 1,434 on potentiometer wire—*i.e.*, 1,434mm. from A—1·434 volts being the E.M.F. of the standard cell for 15deg. C. Then the resistance in the battery circuit was varied until the galvanometer gave no deflection, when the knife-edge made contact with the wire, and the battery closed by the key K^1.

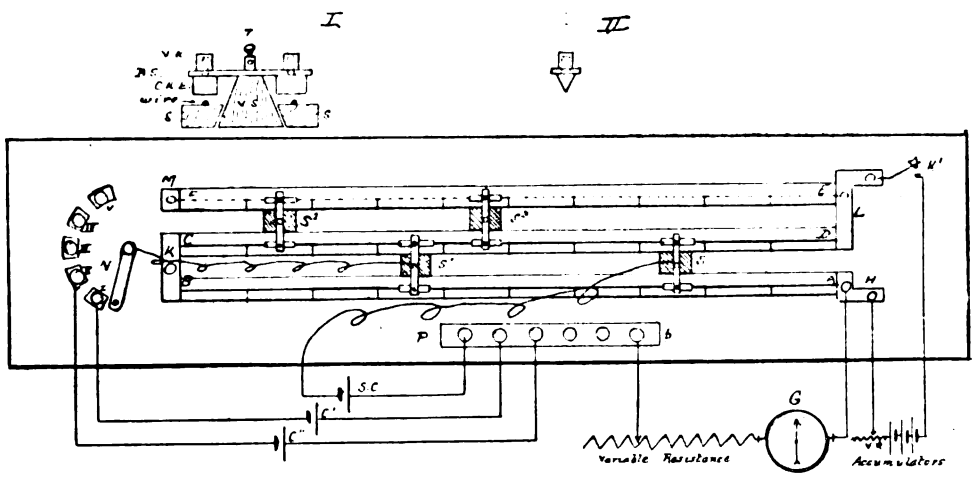

FIG. 5.

T, Terminal. V K, Vulcanite Knob for pressing knife edges down. B S, Brass Spring. C K E, Copper Knife Edge. S, Boxwood Scale. V S, Vulcanite Slider, shaped to slide easily between the scales.

The fall of potential along the wire between A and S was now 1·434 volts, because the E.M.F. of the standard was 1·434 volts; consequently, we knew the D.P., or drop in volts, between A and D was two volts, the 2,000mm. divisions corresponding to two volts. The knife-edge of S was now released, and the arm of N placed on contact-piece I., to put cell C^1 in circuit, and the position of the slider S^1 ascertained when the galvanometer gave no deflection under similar conditions as before. In this case it was found to be at division 1,760, so that the E.M.F. of the Grove's cell was 1·76 volts. In the same way the E.M.F. of other cells may be determined by simply using the slider S^1, by moving the arm of N into contact with the contact-piece connected to the cell under test. Throughout the test the slider S is only used with the standard cell.

It is important to notice that the mean of a number of determinations should be taken, during which it is advisable to repeatedly put slider S down to see if the battery is keeping constant. If not, the resistance in the battery circuit should be varied so as to keep the D.P. between A and D two volts. With care and practice a large number of tests can be made in a very short time, since there is no disconnecting and changing connecting wires. In all cases a high resistance must be inserted in the galvanometer circuit, so that the standard cell does no work. The accuracy of the results may be increased by insulating the battery, galvanometer, and potentiometer on sheets of indiarubber.

(To be continued.)

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 119.)

Since one meets in practice so far more commonly with such straight lines as these, which do not pass through "the origin," as the point O is called, it will be well to look at another way of arriving at the equation to such straight lines. Take, for instance, the line N R P T in Fig. 8. We were content with the evidence of the three curves in Fig. 6 as showing that all straight lines through the origin were represented by an equation of the shape $m x = y$, and the difficulty here is that this line does not pass through the origin which we have taken. Let us, then, take a new origin, say the point N. If this is our

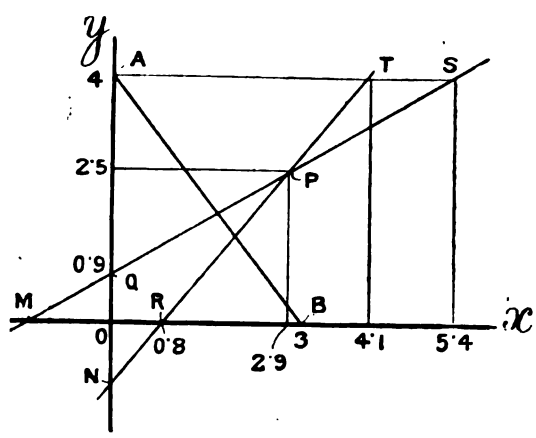

FIG. 8.

origin, we have to measure all distances from this point along our axes, and we have a new axis, which we will call $O^1 X^1$ (Fig. 9). and the point O^1 and the point N are the same, and $O^1 X^1$ is parallel to O X. Obviously all our x measurements are still the same, but all our y measurements must be increased by the length O N or O O^1. These new y measurements we will call y^1, and in all cases $y^1 = y + O O^1$. The distance $O^1 L = O L + O O^1 = O L + 0{\cdot}971$, and the distance $O^1 V = O V + O O^1$.

Point.	x	y	y^1	$\frac{y^1}{x}$
N	0	−·971	0	—
R	0·8	0	0·971	1·214
P	2·9	2·55	3·521	1·214
T	4·1	4	4·971	1·214

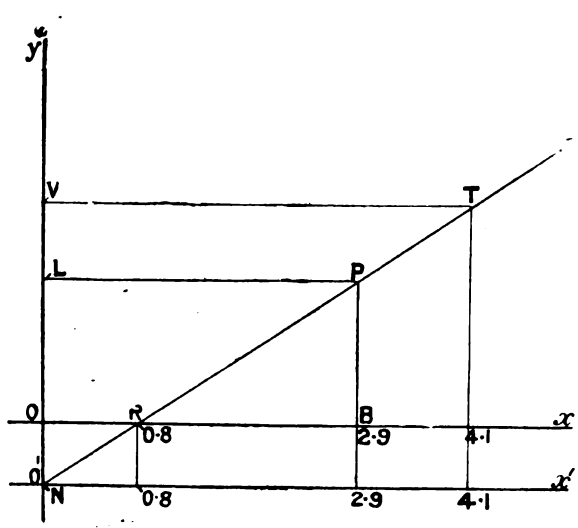

FIG. 9.

And see that $1{\cdot}214 x = y^1$; but $y^1 = y + O O^1$ and $O O^1$ is the same as O N. Now, O N is the Y ordinate of N, and is 0·971, so $1{\cdot}214\ x = y^1 = y + O\ N = y + 0{\cdot}971$; $\therefore\ 1{\cdot}214 x - 0{\cdot}971 = y$, which is what we had above, and the point N is the point where our curve cuts the axis of Y, which value of y we called h.

This expression $m x + h = y$ is known as the general equation to a straight line. We have seen that the equation $x = y$ will represent one particular straight line, but only one; and that $y = m x$ will represent any straight line which passes through O, but that if the straight line cuts O X or O Y not at O we must modify this equation $m x = y$, as we have shown, into $m x + h = y$. Now, this equation $m x + h = y$ fits all the straight lines, for, of course, h may = 0 and m may = 0, for these letters must have any value which will fit the equation to the line. If $m = 0$ and $h = 4$, we find that $m x + h = y$ is the straight line A T S, Fig. 8. The line of which B P is a part is $x = 2{\cdot}9$, for being parallel to O Y it can have any value for y—there is no value of y which cannot be put to this line, but it has only one x value; in this case m is really infinity, and h becomes minus infinity. The values for m and h, in the case of the straight lines M Q P S and N R P T, have been given before.

The object of mentioning all these cases is to make clear that x and y are the variables, but that m and h are arbitrary constants, and we write these letters m and h simply to imply that each curve needs a particular value in their places to make the equation fit it. It has been explained in a previous article that the use of the variables x and y is to indicate that we may give any value we like to one of them, and by simple arithmetic and the use of the values in the places of m and h can calculate the value of the other variable for this value of the first variable. In this way, if we are given the equation to a curve of any description, we can at once find points on it by choosing values to give to one variable—say, x—and then calculating the corresponding values for y.

It may not be superfluous to remark here that for the purpose of plotting curves a special ruled paper, known indifferently as "squared" or "sectional" paper, is sold, and of a quality sufficiently good for most purposes can be purchased at ½d. a sheet (18in. × 10in.).

It is certainly not unnecessary to repeat that *nothing* so thoroughly brings home to the mind the effect of varying the values of m and h as actually plotting curves, using the equation $m x + h = y$, and trying a pair of values for m and h. Then give m a different value and again plot the curve. Do this with several values of m, keeping h the same. Now keep the value of m constant and plot the curve, giving various values to h—for every value you give to h plot a curve. Doing this, though a somewhat monotonous exercise, will make the whole thing clearer than hours of reading or lecturing could possibly do.

It would be well to plot such curves as are represented by the following equations,

$$x = m y^2\ ;\ x^2 = m y\ ;\ x = \log y\ ;\ \frac{x}{a} + \frac{y^2}{b} = 1,$$

using m, a, and b to represent arbitrary constants, as before, and x and y as the variables.

Erratum in last article.—Page 118, three lines below Fig. 8, should read: "here $x = -1{\cdot}58$, m must = 0; now we saw that m meant."

(To be continued.)

NOTES ON HYDRAULIC POWER SUPPLY IN TOWNS—GLASGOW, MANCHESTER, BUENOS AYRES, ETC.*

BY EDWARD B. ELLINGTON.

(Concluded from page 125.)

Comparison of Hydraulic and Electric Power Supply.—It is interesting, therefore, to enquire whether there are any grounds for the assumption that hydraulic power obtained otherwise than from a natural head of water can be used economically for generating an electric current. It so happens that the materials are available for a comparison between the cost of a public supply of hydraulic power and that of electricity obtained from a central station on almost exactly the same scale. The particulars given in

* Paper read at the meeting of the Institution of Mechanical Engineers at Glasgow.

* Including £56,000 for new site and station, started October, 1894. † Including £400 for water rights and £129 for gas lighting. ‡ Wapping station only; output 177,000,000 gallons in 1894. § Davies-street only; output 1,306,794 units in 1894, equivalent to 200,490,000 gallons.

Table II. are taken from the records of the London Hydraulic Power Company and of the Westminster Electric Supply Corporation for the year ending December 31, 1894. In making the comparison, 1,000 gallons of water at 750lb. per square inch is taken as equivalent to 6·518 Board of Trade units of electricity. This analysis shows that the station cost of the hydraulic power is 5·172d. per thousand gallons pumped at the pressure of 750lb. per square inch; while the corresponding cost of an equivalent amount of electric energy reduced to the same hydraulic standard is 9·014d. per thousand gallons; or on the electrical standard of Board of Trade units, 0·793d. and 1·383d. respectively. The output during the year, the capital employed, and the average rate received for both supplies, are nearly the same. The coincidence of the figures is extraordinary, except in the cost items, in which their divergence is equally remarkable. No other conclusion can be drawn than that for some reason or other not hitherto explained hydraulic power is much less costly to produce than electricity. The Westminster electric supply is one of the largest in the country, and its cost is one of the lowest. The London hydraulic supply is the greatest anywhere, and is produced no doubt very cheaply. In neither, however, has the minimum cost been reached, for in both of them the station cost in the newer installations is considerably below the average for 1894. For instance, the station cost of the hydraulic power supply from the Wapping station for 1894 was only 4·177d., as against 5·172d. for the whole supply; while the station cost of the Davies-street station of the Westminster electric supply is equivalent to 8·731d. per 1,000 gallons as against 9·014d. for the whole supply. It may be thought that the low annual load-factor of, say, 0·18 for the electrical supply, as against 0·33 for the hydraulic, accounts for most of the difference; but under the able control of Prof. Kennedy the influence of a low load-factor has been to a great extent neutralised by running the machinery actually in use at nearly full load. Moreover, the figures of other electric installations, such as the St. James's and Pall Mall, where the load-factor is much higher than in the Westminster district, show a similar difference of cost as compared with the hydraulic supply. Now it is obvious from the figures of the London and Westminster installations that, as the output during the year was the same, while there is so great a difference in the annual load-factor, the maximum horse-power employed is much greater for the electric than for the hydraulic supply; but the output per unit of capital outlay seems to be much the same. This is no doubt owing to the greater concentration of demand in the area supplied with electricity. If a large amount of power is concentrated in a single station, it is practicable to work that station much nearer to its maximum capacity than if the same power had to be supplied from two or three stations. In the London hydraulic supply, while the annual load-factor is 0·33, calculated on the maximum delivery at any time during the year, the load-factor of the whole plant in use during the year under the most favourable conditions is only 0·20, and is often much lower; in other words, more than one-third of the whole plant is always in reserve, and in some years as much as half. The proportion of plant out of use altogether or not running at full load at the periods of maximum demand is no doubt much less at most electric lighting stations, and the load-factors of the two systems calculated upon the total station plant probably do not differ widely. The fact that the load-factor calculated on the maximum flow is lower for the electric supply than for the hydraulic does not, other things being equal, account for the larger part of the difference of cost. This is shown also by a comparison of the cost of the hydraulic supply during a week when the output is large and during another when it is small. During the week ending October 18, 1894, altogether 9,095,000 gallons were pumped at the London hydraulic power stations, and during the week ending December 27, 5,902,000 gallons only. The increased cost for fuel in the latter week was 0·317d. per 1,000 gallons, and for wages 0·77d. per 1,000 gallons, making 1·087d. per 1,000 gallons; whereas the average excess cost of the electric supply is more than 3½ times as much, and in the item of coal nearly five times as much. The immediate question, however, is the economy of using hydraulic power for generating electricity; and it will be seen from the foregoing figures that, with a loss of 33 per cent. of the hydraulic energy during conversion into electric energy, the station cost of 0·793d. per Board of Trade unit would rise to 1·189d., or 0·194d. below the cost 1·383d. of the direct current of the Westminster supply. The cost will be further increased by the wages, superintendence, and repairs at the converting stations; so that on the whole there does not seem much probability of any economy resulting from this method of generating electricity on a large scale. It

Digitized by Google

may be mentioned that the principal reason which led the late Prof. Van Rysselberghe to advise the combined method for the electric supply of Antwerp was that he considered the losses of distribution of the electric current would be much less on that method. The losses of distribution, however, are not very serious either way; and the direct or the combined method must ultimately stand or fall, the author considers, on the relative generating cost per unit. Mr. L. Moris has kindly furnished the particulars in Table III. of the working of the Antwerp hydraulic service. The very low cost per thousand gallons pumped is evidently due to the small amount of wages paid at the central station, and the figures include nothing for superintendence, water supply, lighting of station, removal of ashes, or repairs to machinery. At least 1½d. per thousand gallons should be added for these items in order to make the cost comparable with that of the London stations. It will be noticed that the reduced output in April increased the cost only 0·46d. per thousand gallons, or, say, 15 per cent., while the output was only 58 per cent. of that in January. It seems, however, that notwithstanding the low cost at which the hydraulic supply is obtained in Antwerp, the general results of the combined method during the first nine months of working have not been satisfactory. It is stated that the arrangements have proved more costly than the usual direct method, not only in first cost, but in working expenses. The capital outlay per electric unit would probably be greater, but there seems no sufficient reason why the working expenses should be increased. Further information is required before an explanation can be given. While the combined method does not seem to have any sufficient basis for a general system of distribution, it is evident from the foregoing figures that electricity can be economically generated by means of hydraulic power artifically obtained; and the latter can therefore be used with advantage as a supplement to ordinary methods of generating electrical energy. Hydraulic power is clearly much the most economical in those applications where the direct pressure can be utilised—such as for lifting and pressing. Where rotary motion is needed, the special circumstances of each case will determine what power shall be used, and all are now more nearly on a par as regards cost. For motors running regularly for several hours a day the London hydraulic power stations now supply power at a rate of 1s. 6d. per 1,000 gallons, which is equivalent to 2·76d. per Board of Trade unit of electricity, or, say, 3d. per brake horse-power per hour. It is questionable whether small powers can by any means be obtained at a lower rate when all the items of cost are taken into account.

Hydraulic Power Supply for Drainage.—Hydraulic power mains have recently been put down in the streets of Buenos Ayres for the purpose of drainage, and although the supply is not intended to be sold to the public, yet the conditions are such as to render interesting a general outline of the undertaking as an instance of a hydraulic power supply in towns. As engineer-in-chief to the works, the Hon. R. C. Parsons had a few years ago to face the problem of draining the two low-lying Boca and Barracas districts. In order to avoid the great cost and difficulty of laying deep sewers, he ultimately decided to lay out the works on the plan of numerous small automatic pumping stations, and finally adopted hydraulic power as the best means for working the pumps at the sumps. There is a central station, containing two compound surface-condensing horizontal engines, having cylinders 15½in. and 27in. diameter with 22in. stroke; each engine works direct a double-acting pump of 5in. diameter and 20in. stroke, and is capable of delivering 175 gallons of water per minute at 58 revolutions. Space has been provided for a third engine, whenever the work to be done at the sumps renders it necessary. There are three Lancashire boilers, 6ft. diameter by 22ft. long, with a Green's economiser of 120 tubes. The roof of the engine-house is a tank, which is kept supplied from the waterworks mains. The water after use is run to waste into the sewers. The engines can be run with or without the condensers, as it is sometimes inconvenient to use the water in the tank for condensing purposes, owing to the high temperatures during the hot season. There are two accumulators of 18in. diameter and 20ft. stroke, which were loaded at the trials to 800lb. per square inch; but the machinery is calculated to work at 750lb. per square inch under ordinary conditions. The station is fitted out with the usual accessories. The mains carried through the Boca and Barracas districts are nearly 8½ miles in length. There is a duplicate supply to every sump. The largest mains are 5in. bore, and the smallest 2in. bore. There are in all 17 sumps. Each sump contains duplicate hydraulic sewage pumps on the author's system. The quantity of sewage to be dealt with varies considerably at the different sumps, but it was found practicable to reduce the whole of the pumps to two sizes, and as a matter of convenience the only substantial difference between them was made in the stroke. They are all single acting, and have plungers 30in. diameter; 22 of them are made with 3ft. stroke, and 12 with 4ft. stroke; the maximum speed of working is 10 double strokes per minute. The head of water and friction on the delivery sewers are also different at the different sumps, and the diameter of the hydraulic working rams was varied to suit. The pressure on the side rams, which perform the up stroke, is constant; the water from these rams is returned in the down stroke to the central hydraulic cylinder. The sewage runs into the sumps by gravity, and when they are nearly full a float starts one of the pumps, and when the level falls a certain amount the float stops the pumps. If the level of sewage continues to rise after the first pump is at work, another float starts the second pump. The pumps therefore always work so as to cause a flushing velocity in the rising main or sewers. The exhaust power water is discharged into the sewage-pump cylinders, thus serving to dilute the sewage and keep the plungers clean. The whole arrangement is automatic. At the time the machinery was completed, there were no houses connected to the sewers, so that the tests had to be made with water run into the sewers for the purpose; the results of the engine tests are given in Table IV. The delivery sewers discharge at different points into the main outfall sewer, which is everywhere above the level of the Boca and Barracas drainage area. The whole of the mains were tested to 1,500lb. on the square inch after being laid. In laying them during the hot weather it was found necessary to protect them from the heat of the sun, in order to preserve their correct length. The whole of the work, including all the mains, was prepared in such a way that it was unnecessary to obtain any making-up pieces in Buenos Ayres, and all the machinery for each sump was erected in the workshops at Chester before being sent out.

It will be seen from Table IV. that the coal per indicated horse-power was 1·891b. per hour, and per pump horse-power 2·291b. per hour. Taking the average efficiency at the sewage pumps at 50 per cent.,* including all losses in the mains and valves at the highest speed contemplated, the expenditure of coal is 4·581b. per pump horse-power at the sumps. This shows that 41 per cent. of the indicated horse-power of the engines is recovered in useful work at the sumps. The pumps have to work under most variable conditions, and are situated at 17 sumps distributed over an area of nearly two square miles, requiring over eight miles of mains to connect them with the central station. The economy to be obtained under such circum-

* The actual efficiency of the pumps with the higher lifts of 20ft. to 28ft. was considerably more; but at the lower heads of 10ft. to 15ft. the efficiency was necessarily reduced.

TABLE IV.—Hydraulic Power Supply for Drainage in Buenos Ayres. Trials of Two Compound Horizontal Condensing Pumping Engines at Central Station.

November 21-22, 1893.	Engine No. 1.	Engine No. 2.
Duration of trial, hours	10	10
Diameter of high-pressure cylinder	15½in.	15½in.
Diameter of low-pressure cylinder	27in.	27in.
Stroke	22in.	22in.
Revolutions, total during trial	35,150	35,030
Revolutions, average per minute	55·58	58·38
Indicated horse-power, mean	119·131	120·757
Water pumped at 800lb. pressure per square inch, total during trial, gallons	106,293	105,931
Water average per minute, gallons	177·15	176·55
South Wales coal feed into furnaces, total during trial, ash, etc., not deducted, pounds	2,354·61	2,192·47
Coal per indicated horse-power per hour, pounds	1·97	1·81
Coal per pump horse-power per hour, pounds	2·37	2·22
Boiler pressure per square inch above atm., pounds	100	100

stances cannot be great, and it is believed that no other method of distribution has shown such good results under similar conditions. The Hydraulic Engineering Company, Chester, were the contractors for the construction and erection of the whole of the plant; Mr. F. W. Thornton had charge of the erection of the machinery and laying of the mains for them. Hydraulic pumps of the same kind as those at Buenos Ayres have been for some years at work, pumping the water from the River Thames into the reservoir tanks at the London Hydraulic Supply stations. At Falcon Wharf, Blackfriars, the head is about 80ft., including friction in the rising main; and the efficiency of the pumps is 75½ per cent.

THE BEHAVIOUR OF TRANSFORMERS UNDER THE INFLUENCE OF ALTERNATING CURRENTS OF VARIOUS PERIODICITIES.

This was the title of the paper which Dr. G. Roessler, of Berlin, read at the recent meeting of the Verband Deutscher Elektrotechniker at Munich. The paper is a very elaborate one, and is elucidated by numerous tables of figures and diagrams. The author says that the general definition of an alternating current as an electric current whose strength periodically alters is only a half definition, since the general formula which describes each periodical variation consists of a number of sines, and its determination for every special case of an alternating current differing from the sinus kind offers difficulties, and it has been usual to solve all alternating-current problems under the supposition of a pure sinusoidal flow of the alternating current. This process is only justified if by the experiment and by theoretical consideration it is shown that deviations from sinusoidal variations do not substantially affect the behaviour of the alternating current in its technical applications. To what extent such an influence exists is, however, a question still unanswered.

Three items for the technical application of the alternating current come into consideration: lamps, transformers, and motors. As to lamps, in regard of incandescent lamps it is not questionable, according to the action of the current, that independent of the curve of the alternating current the same illuminating power results if the average value of the quadrates of the current intensity is the same. In respect of arc lamps, the influencing of the illuminating power by the form of the current curve required a special investigation. The author reported at the previous meeting of the Verband upon a number of measurements which endeavoured to frame a reply to his question. They manifested that the illuminating power of alternate-current arc lamps is very considerably dependent on the nature of tension and current curves, so that the illuminating power is greater in proportion as the alternating current retains its maximum value, and therefore the flatter the current curve is.

Regarding the influence of the periodical ebb and flow of the alternating current on the action of transformers and motors, opinions are still very much divided. It was in view of this difference of opinion on a matter of importance to those interested in alternating currents that the author conducted a series of experiments with an alternate-current transformer in the electrical laboratory of the Technical High School in Berlin, which experiments he describes in detail in his paper. The current for feeding the transformer was supplied by two alternate-current dynamos, also in the laboratory, which were especially adapted for the investigations, because one of them gave a very pointed tension curve, while the curve of the second was almost sinusoidal.

The first is a four-pole 5·5-kilowatt machine, by Ganz and Co., with revolving magnet cross; the second, an old small 480-watt machine, by Wechlser and Co., with four poles on each side of the four-coil revolving armature. For the comparative investigation with both machines, only an old 480-watt transformer could be chosen on account of the inferior capacity of the smaller of the laboratory transformers. This old small transformer does not, of course, represent the present stage of transformer construction. The iron core consisted of 78 E-shaped wrought-iron plates 0·5mm. thick. The plates lay alternately inversely upon one another and were insulated by silk paper. They were held together by a wooden frame. The total weight of the plate was 8·168 kilogrammes. The primary coil consisted of 132 turns of 2·7mm. copper wire; the secondary of 265 turns of 1·8mm. copper wire. For estimating the primary and secondary tensions, Cardew voltmeters were used; for measuring the primary pressure a Thomson instrument was employed; for the secondary, a Siemens and Halske electrodynamometer. The primary effects were given by a Helios wattmeter, while the secondary capacity, as the load of the transformer was exclusively through incandescent lamps, was obtained by multiplication of the values for the secondary tension and the secondary pressure.

In summing up the experiments, the author says: There remain (1) the difference of the losses of effect in the iron, as these only depend on the value of the primary tension and their frequency; (2) the variation of the primary pressures, even if the secondary current has phase retardation against the secondary tension; (3) the ground for the differences of the magnetic dissemination is independent of the nature of the resistance in the secondary circuit, and therefore a difference of the fall of tension in the same sense by loading with induced resistances is also to be expected. It is shown that the use of peaked tension curves, so far as relates to effect-consumption and the value of the primary pressures, supplies much more favourable results than the use of sinus lines or of still flatter curves. Against these great advantages of pointed tension curves is, however, to be placed a disadvantage in the shape of the large secondary loss of tension. The percentage variation of this fall of tension was in the case under notice much less than the variation of the primary pressures and effects, and may therefore be no great obstacle to the use of peaked curves if several transformers work on a specially-arranged secondary network, whose tension is automatically regulated direct from the central station.

On the whole, the author thinks that the superiority of the one or the other machine must be decided by the load diagram of the installation and the transmission distance. If short-distance work, which during the greater portion of the day only reaches a small portion of its maximum value, be in question, as in the case of a central station near a town which distributes power and light to many consumers, the use of peaked tension curves presents the probability of great economy. For power transmission to long distances, on the other hand, the use of flat tension curves will be more advisable. These results refer to the behaviour of transformers alone. The inferior illuminating power of arc lamps with peaked curves sinks the scale more to the side of the flat curves. But to arrive at a definite conclusion upon every point, Dr. Roessler adds, we must have the results of the investigations of the behaviour of motors.

IRON AND STEEL INSTITUTE.

In our issue of the 5th ult. we gave a list of the papers which are to be read at the autumn meeting of the Iron and Steel Institute, which will take place in Birmingham on the 21st, 22nd, and 23rd inst. The following additional papers will also be read: "The Production of Iron by a New Process," by Mr. R. A. Hadfield; "The Iron Industry of the South of Russia," by Mr. George Kamensky; and "The Analysis of Ferro-Chromium," by Mr. E. H. Saniter. These make the total number of papers thirteen. The outline programme for the meeting is as follows: Monday, August 19.—The secretaries' office will be open from 2 p.m. to 6 p.m. in the Council House, Birmingham, for the registration of addresses, issue of badges of membership, programmes, invitation-cards, etc. Tuesday, August 20.—9 a.m., secretary's office open in the Council House, meeting of council in committee-room; 10 a.m., reception of the president, council, and members of the institute by the Mayor of Birmingham and the members of the local reception committee, reading and discussion of papers; 12.30 p.m., adjournment for lunch; 2 p.m., visit to industrial establishments in or near Birmingham, the list including the following alternative excursions: (*a*) to the works of the Electric Construction Company, Wolverhampton, and of the Great Western Engine Works, Wolverhampton; (*b*) to the works of Messrs. Thomas Parker and Co., electrical engineers, Wolverhampton, and of the Staffordshire Steel and Ingot Iron Company, Bilston; (*c*) to the surface works of Hamstead Colliery, Birmingham; (*d*) to Tangye's Engineering Works, Smethwick; (*e*) to the works of Messrs. Baldwin and Sons, paper manufacturers, King's Norton, or (*f*) members not taking part in the foregoing excursions may visit Messrs. Elkington's electro-plating works, Messrs. Gillott's steel pen works, Messrs. F. and C. Osler's glass-works, the municipal gasworks (Windsor-street 9 a.m. to 11 a.m., Duddeston Mill-road, Saltley, 11 a.m. to 1 p.m.), the works of Messrs. J. Hardman and Co., stained-glass and church decoration work, the works of Messrs. J. Cartland and Sons, brassfounders, and the works of the Birmingham Electric Supply Company, 4 p.m.; 8 p.m., conversazione and reception in the City Council House and Art Gallery by the Mayor of Birmingham. Wednesday, August 21.—10 a.m., reading and discussion of papers; 12.30 p.m., adjournment for lunch. The afternoon will be devoted to—(*a*) An excursion to Worcester, where the Guildhall, the cathedral, and the works and museum of the Royal Porcelain Company will be visited. There will also be alternative excursions: (*b*) to the Earl of Dudley's Round Oak Iron and Steel Works, Limited, Brierley Hill; (*c*) to Webb's gasworks and local fireclay works at Stourbridge; (*d*) to the Birmingham Small-Arms Factory, Small Heath, and to the Government Small-Arms Factory, Sparkbrook, or (*e*) on application to the secretary, arrangements will be made for members who desire it to visit on this day Sandwell Park Colliery, the wagon works of Messrs. Brown, Marshalls, and Co., Limited (Adderley Park, Birmingham), the works of Messrs. Taylor and Challen, engineers, Birmingham, or the revolver works of Messrs. Philip Webley and Sons; 8 p.m., entertainment in the Botanical Gardens, Edgbaston, by invitation of the local reception committee. Thursday, August 22.—10 a.m., reading and discussion of papers; 12.30 p.m., adjournment for lunch. The afternoon will be devoted to an excursion to Stratford-on-Avon, under the direction of Sir Arthur Hodgson, K.C.M.G., chairman of the trustees for Shakespeare's birthplace. The members joining the excursion will visit Shakespeare's birthplace, the Shakespeare Memorial Buildings, Holy Trinity Church, and King Edward's Grammar School. They will afterwards, by invitation of the local reception committee, have tea in the Stratford Town Hall, and at 7 p.m. there will be a short entertainment consisting of Shakesperian recitations in the Memorial Theatre. The train will return to Birmingham about 8.30 p.m. Friday, August 23.—The members and ladies accompanying them will leave Birmingham by special train to visit the ruins of Kenilworth. They will then proceed to Warwick, where they will have lunch, and in the afternoon they will be received at Warwick Castle by the Earl and Countess of Warwick, who have invited them to tea. The museums and laboratories of Mason College will be open to inspection by members under the guidance of Mr. W. G. McMillan, lecturer on metallurgy, on August 20, 21, and 22, from 9 a.m. There will also be shown there a special collection, illustrating local industries, comprising raw materials, and finished or semi-manufactured goods, illustrative of the processes used.

THE ELECTRIC LIGHTING OF WIMBLEDON.

In accordance with the instructions of the Wimbledon District Council, Mr. A. H. Preece has prepared an elaborate report with alternative schemes for lighting the streets of the town with electricity, and for the general supply of electricity to the district. The report is as follows:

It cannot now be urged that electric lighting is in its infancy, or that it has not been carefully considered by those towns which have adopted it. You yourselves, when a Local Board, had the question frequently before you after my father first gave you a report on the question in 1884. Town Councils and other local bodies have for many years been considering the matter, and few of them have decided to do other than establish their own stations, while many of those who have transferred their powers are now doing their utmost to purchase them back to prevent the companies from establishing in their districts powerful monopolies and large dividend-bearing concerns. As an example, I may instance Liverpool and Manchester. The Liverpool Corporation allowed a company to start which they are now going to buy for about £400,000; this is about 50 per cent. on the shares, although the business has only been started on a large scale three or four years. Manchester was more far-seeing, and they are now with a capital expenditure of £150,000 making an annual profit of £4,000, which is increasing at a marvellous extent; while Brighton, with a capital expenditure of £119,382 made last year a profit of £4,500 after paying interest and repayment of loan.

It is interesting to note that no less than 42 towns have now established central stations for the supply of electricity, while over 30 more are actively engaged in establishing similar works. Among others, I should mention small towns such as Bootle, Burton, Burnley, Dewsbury, Yarmouth, Whitehaven, Kingston, Ealing, Cheltenham, Nelson, Taunton, Abergavenny, Basingstoke, Chichester, Eccles, Llanelly, Monmouth, Tunbridge Wells, etc. The capital invested by corporations in electric lighting now exceeds £2,500,000, and every week one may read in technical papers of Local Government Board enquiries being held for new loans and for extension loans. Most of the towns mentioned above have lighted some of their principal streets with electricity, but they have nearly all been contented with installing a few large arc lamps. The only town which has lighted its streets entirely with arc and incandescent lamps is Whitehaven, but other towns have allowed local companies to do so at fixed prices per lamp. At Whitehaven it has been a most marked success financially. Their last year's figures showed that the cost had been less than gas, and the estimated figures for this year show a profit. Portsmouth lights its streets with arc lamps up to midnight, and then incandescent lamps are lighted. Their figures for the short time they have been running are extremely good.

The proper and good illumination of the streets is the function of the local authority. It facilitates locomotion, it adds to the security of premises, it aids police supervision, it prevents accidents, and where a general supply of electricity to consumers is installed it greatly facilitates business. It is frequently said that a town which establishes an electric light station is fostering an industry which solely benefits the wealthier class; but if the streets are well lighted all classes are benefited, and everyone expresses an interest in the undertaking.

I think it is universally considered that the streets, at any rate the main streets, of Wimbledon, require better illumination. Oil lamps are undoubtedly cheap, and therefore if you are to improve the lighting it must be borne in mind that it can be done only by a somewhat larger expenditure. If you added oil lamps of larger power or if you increased the number of lamps, your annual expenditure on lighting would naturally be larger. I therefore ask you to bear in mind that if the lighting of your streets by electricity is to be done, it must be well done, and you must be prepared to expend more money per annum in so doing. I hope, however, to be able to show that by adopting electricity the cost of lighting your streets will not be so great as if you increased your oil lamps or if you had gas, while, by the aid of private lighting, which is undoubtedly wanted by many shopkeepers and residents, you will be able to materially reduce the cost of the street-lighting by placing the profit made in the private lighting to the credit of the cost of the street-lighting. This is undoubtedly a perfectly fair mode

Digitized by Google

of procedure. The shopkeepers and owners of large private houses are those who generally require good street-lighting. The former like it so that their customers may be induced to use the streets at night, and the latter want it to be able to drive safely about late at night to their friends' houses.

The present cost of lighting by oil averages £2. 9s. 6d. per lamp, and there are about 725 lamps placed in your streets. The total cost of lighting is thus approximately £1,800. If gas were installed in place of oil the cost would be, according to Mr. Cooper's report to your committee, about £4. 11s. 7d. per lamp ; therefore the total annual cost would be about £3,320. But it must be recollected that the gas company refuse to supply lamps more than 100ft. away from existing mains unless the cost of connecting them is defrayed by the Council. This would be the case with quite 200 lamps, and it would necessitate a heavy new capital expenditure.

I understand that it is the wish of many members of your Council that two schemes should be considered—one embodying the lighting of the whole district, and the other the lighting of only the main streets. In both schemes you are bound to consider the demand for private lighting. This is, of course, only guesswork, and I have only the experience of other towns to work upon. It is interesting to note that in every town I have been connected with, the demand for current always rises where least expected. But it is certain that lamps will be thickest where shops are situated, and also that the residents in the larger houses will be the first to adopt electricity. The scheme, whether for a small number of lamps or a large number, will necessitate establishing a generating station in a cheap and convenient position. It was necessary to fix this before any estimate could be prepared. I have carefully considered the question of site, and I find that the sewage farm is practically the only suitable ground. It is somewhat distant from the centre of Wimbledon, but by placing it so far away it is not likely to be a nuisance. There is plenty of land, available water is abundant, and it will be possible to use condensers and thus save 25 per cent. on the coal bill. Again, there is already an engineering staff there, which can be added to, and the whole used to run the sewage pumps and the electric light engines, etc., and thus materially reduce the expenses. I have therefore in my estimates assumed that the generating station will be at the sewage farm. In the two schemes I submit I have only estimated for incandescent electric lamps. I cannot recommend the arc lamp for the general lighting of your streets. Arc lighting is the proper lighting for crowded city streets, and as an advertisement to the electric light. But it is too brilliant and too expensive for country roads. However, if it is desired to place a few arc lamps in the Broadway, or in Hill-road, or High-street, it can easily be done. The same mains will do for the purpose. But it will be necessary to spend a little more money both in capital and maintenance. The fixing of an arc lamp will cost about £25, including the pillar. The maintenance will be from £16 to £20 per annum, according to the number of hours it is in use.

In the scheme for lighting the whole parish I have estimated for 1,000 lamps of 32 c.p. for the public lighting, and 5,000 lamps of 8 c.p. for the private lighting. The public lamps can be of any size providing that the total number installed does not exceed the equivalent to 1,000 32-c.p. lamps. I recommend that in the main streets—such as the Broadway, Hill-road, and High-street—50-c.p. lamps, or two 32-c.p. lamps, should be fixed in each of the small posts, and in the larger posts either one 100-c.p., two 50-c.p., or three 32-c.p. lamps should be placed. But at midnight (and I have estimated for this in the mains) half of the lamps would be turned out. This can easily be done by the simple turning of a switch placed at some convenient spot. As regards the private lighting, I have estimated for 5,000 8-c.p. lamps fixed in private consumers' premises. The total number of these lamps burning at one time is not likely to exceed 3,000, and the plant provided will provide for this demand. The following are the streets in which I have allowed for private consumers : The Broadway, Merton-road, Hartfield-road, part of Haydon's-lane, Worple-road, Hill-road, High-street, Ridgway, Copse-hill, Park-side, South-side, Church-street, Arthur-road, and Wood-side. Specially heavy mains have also been provided for the shop areas in the Broadway, Merton-road, Hill-road, and High-street. This scheme, briefly summarised, shows that with a capital expenditure of £31,000, and for a total annual cost of £2,350, you will be able to light your streets at an extra cost of 15s. 2d. per lamp, providing a demand for 3,500 private lamps arises. That is to say, the extra cost of lighting your streets by electricity will be £550, and the result will be that instead of having 725 lamps which give at their best 20 c.p., you will have the equivalent of 850 lamps giving 32 c.p.—that is quite double the present illumination.

If it is assumed that there are 5,000 private lamps connected to the mains, then the expenses will be raised by £350, and the revenue will be increased by about £750. The balance is then reduced to £150. I feel confident that before many years the profit on the private lighting will be sufficient to enable you to light the streets for almost nothing. Every new lamp will bring you in a profit of from 3s. to 4s. per annum. Therefore, if you obtain in a few years' time a total of 15,000 private lamps, you will be able to light the streets for nothing. There is no reason why you should not reach this total soon. In Hampstead the station has not been started a year, and they already have nearly 10,000 lamps connected and applied for. Neighbouring districts could also obtain light from your station without great expense or any difficulty.

In the second scheme, which provides for the lighting of the main streets only, I have estimated for a plant to light 600 32-c.p. public lamps and 3,000 private lamps. I have estimated for the replacement of some 400 of the existing public lamps. The following will be the streets in which the proposed new lamps should be placed : Broadway, Merton-road, Hartfield-road, High-street, Ridgway, Copse-hill, Worple-road (part of), Southside, Parkside, Church-street, Arthur-road, and Wood-side, and small portions of adjacent roads. This scheme, briefly summarised, shows that with a capital expenditure of £20,000, and a total annual cost of £2,310, you will be able to light about 400 of your lamps at an extra cost of £1. 6s. 6d., including 325 oil lamps, provided a demand for 2,500 private lamps arises.

Even assuming that the private lighting is not taken up to the extent anticipated by me, I cannot see that it is possible for the annual cost of lighting by electricity to exceed the estimated cost of lighting by gas. With only 1,000 private lamps connected I do not think the annual cost of lighting the streets would exceed £3,000.

The lighting of streets by incandescent lamps is rapidly being improved. It has been tried in the City of London, but here, as well as in some other cases, the mixing of the brilliant white arc lamps and the yellow glow of the incandescent lamps has not been very successful. In England, street-lighting by incandescent lamps may be seen in successful operation at Chelmsford, Weybridge, Woking, Fareham, Whitehaven, and Portsmouth. In Ireland there are a few towns so lighted, while in Germany and America especially, many towns have incandescent lighting. At Chelmsford a local company charge the corporation £2. 5s. 6d. per 32-c.p. lamp. If a company can afford to do satisfactory lighting at that price, it should be within the province of a local authority to work at no greater outlay. At Kingston, though a loss has been made up to the present, the revenue for the quarter ending March, 1895, was more than double that of the previous March quarter, and the working expenses were no greater.

I have based all my figures on actual experience. I do not think that any will be exceeded. The working expenses will, however, depend greatly on the skill and ability with which the station is managed.

The system proposed is that known as the high-pressure alternating-current system. It is the only practical system that can be used for the Wimbledon district owing to the large and scattered area that has to be served. By means of high pressure one is able to transmit large power over great distances with very small cables. It is analogous to a high-pressure supply of water. A low-pressure system would entail an expenditure of £30,000 or £40,000 in copper mains alone. The high-pressure current will be transformed down at fixed points in the streets and also at large consumers' premises to a low pressure, which is distributed by means of other cables to the various public lamps and small consumers.—[A report of the proceedings of the Wimbledon Council in connection with this matter will be found among our "Business Notes."]

CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

The forty-eighth ordinary meeting of this Company was held on Wednesday at the offices, 58, Old Broad-street, Mr. C. W. Parish occupying the chair.

The **Chairman** moved the adoption of the report, which recommended a dividend of 8 per cent. per annum. He said the traffic receipts for the half-year amounted to £29,164, or an increase of £5,976 ; but this increase was quite abnormal, and resulted entirely from the unfortunate revolution now going on in Cuba. Many of the land lines at the eastern end of the island had been destroyed by one party or the other, and, consequently, senders of messages had been glad to avail themselves of the Company's lines. The expenditure was £6,118, or an increase of £1,105, but part of this sum was due to income tax adjustment, leaving the actual working increase only £817. They had thought it advisable to add £1,500 to the reserve fund against loss on deposits in banks, for business had not revived so quickly as was expected in either South America or Australia, and the first duty of the directors was to be on the right side. A sum of £3,540 remained as balance to carry forward, and they were also able to place £13,638 to the reserve fund. They were especially glad to be able to strengthen their reserve in that way, for he was bound to prepare the shareholders for the fact that a reduction in tariff appeared to be very imminent. The directors had warned them of the change from time to time, and they had staved it off as long as possible. It was most necessary that their financial position should be as strong as possible. In conclusion, he said their cables were working well, and were in excellent order.

Mr. G. Keith seconded the motion, which was adopted.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

CONDUIT WIRING.

The report of Prof. W. E. Ayrton on the tenders for the electric lighting of the North-Western Fever Hospital, given elsewhere in this issue, will be read with a considerable amount of interest. In the first place, there will probably be no differences of opinion as to the advisability of a conduit system for new buildings, and where possible for old buildings. There may be cases, however, where such a system is impracticable. Another point will excite differences of opinion—namely, that referring to the use of metallic conduits. There is no doubt but that the use of metallic conduits does open up a source of trouble. Much of the wiring that is carried out in this country is bad—to use a simple expression—and this bad work is better than much which is carried out in other countries, especially—if our information is correct—in the States. Specifications for public buildings such as this upon which Prof. Ayrton reports are far more stringent in the use of good materials than small private customers. The latter are all for cheapness, except in the matter of talk, and generally get better work than they bargain for, while the former are not so pinched for funds nor so exacting as regards lowness of prices, and usually get worse work than is paid for. This, by the way, is not true only of electrical work, but of all their work. Assume, then, that the insulation is all that is required, the metal conduit may be all right and cause no particular danger; but, on the other hand, if the insulation at any point be not up to the mark, the metal conduit will, as we have previously said, prove a weak point in the lighting. Is there any particular necessity to trouble much about mechanical strength? Surely, in a properly-designed conduit system for internal wiring mechanical strength is of secondary, if not of tertiary, importance. What are really the primary requirements? In the first place, there ought to be absolute immunity from danger of fire. That stands far and away before all other requirements. Then we must have accessibility, ease of examination, ease for rewiring, for extension, no defacing of walls or ceilings, and no interference with decorations. There must be absolute continuity of conduits, and due provision for cut-outs, switches, and drainage. It seems, upon an examination of these requirements, that mechanical strength plays a somewhat unimportant part except at bends and junctions. Prof. Ayrton prefers zinc to earthenware for mechanical reasons. In our view, the latter is preferable for electrical reasons. The question of jointing bends to straight pieces presents no very great difficulty nowadays, nor need there be any particular fear of infringing patents. There is no difficulty of getting as good alignment with one class of tube as another. Of course, if the metal tube is glazed in the interior, it couples both mechanical strength and defence to short-circuits and fire. Again, we must guard against any words being taken as damaging to a conduit system, for we agree with other writers that "the use of conduits affords the only safe, reliable, and permanent method of wiring for electric lighting." With regard to this part of the subject, the plain moral is that metal conduits

Digitized by Google

involve better insulation, and if this is not obtained tends to danger. The cost throughout is much greater, and the difficulty is to find the compensating advantages.

There is one other topic involved in this report which we mention only to emphatically condemn. Prof. Ayrton says: "I specified—*Samples of the conduit which the contractor proposes to use for protecting the conductors from abrasion, vermin, damp, etc., must be sent with the tender.*" With all due respect to Prof. Ayrton, this is not specification at all; it is merely an indication of "instability of knowledge," or of "instability of determination," or the following of a fashionable method of procedure. In the case of Prof. Ayrton, there is no lack of knowledge and no lack of determination; hence we must conclude that he merely follows a fashion—and this fashion, we say, is bad. It is not the place of contractors to say what they will do: it is the place of the consulting engineer to say what is to be done. The specification should have been clear. If the consulting engineer's opinion was in favour of a conduit system, he should have specified the material and size of the conduits, the material and size of the boxes, of the cut-outs, etc. There should have been no option given to the contractor. Failing this, it is impossible to say whether the prices of the tenders are good, bad, or indifferent. There is no earthly use in having a consulting engineer to specify general ideas—anybody can do that, even the much-maligned "electrical plumber." A consulting engineer should be master of his subject, his specification should be a specification, and not a loose statement that the contractor must comply with the fire insurance or the Board of Trade rules and regulations. Either the consulting engineer is capable of providing a scheme or he is not. If not, give up the attempt; if capable, specify it so that the tenders may be viewed from the same standpoint. Can you imagine a Great George-street engineer specifying a bridge by means of a few general ideas and asking contractors to provide tenders and designs on those lines? If Prof. Ayrton is in favour of zinc, iron, glass, or earthenware for the conduits, he should have specified his favourite material and let the contractors all tender for that material, and not have followed in the way of fashionable generalities. What was his estimated cost? and for what? Usually the engineer or architect gives an estimate as a guide to his employers. Why is not this plan followed by electrical consulting engineers?

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CONCERNING FUMING SULPHURIC ACID.

SIR,—The so-called Nordhausen or fuming sulphuric acid ($H_2S_2O_7$) is a compound of a molecule of ordinary sulphuric acid (H_2SO_4) with a molecule of sulphuric anhydride or sulphur trioxide (SO_3); by heating the fuming acid the molecule of SO_3 is readily driven off.

Nearly every text-book on chemistry informs the student that this acid is still manufactured in Nordhausen, in Saxony, Germany. As a matter of fact it was never manufactured in the said town, but in Goslar, a couple of miles from Nordhausen. At the present time, however, this acid is not manufactured at all either in or near that place; but this particular chemical branch is, practically speaking, monopolised by the large chemical concern of Johann D. Starck und Söhne, near Prag, Böhmen, Austria. They produce it in the old-fashioned manner by distilling green vitriol or ferrous sulphate: $Fe_2(SO_4)_3 = Fe_2O_3 + 3SO_3$. The anhydride thus given off is absorbed by rain-water or sulphuric acid 66deg. Beaumé, thus producing fuming acid.

About 25 years ago, Prof. Cl. Winxler, of Freiburg, suggested the use of platinised asbestos as a "catalytic" substance for the union of pyrite—or brimstone—kiln gas (SO_2), sulphur dioxide, with the oxygen of air. The most favourable proportions are 29·6 vol. SO_2 + 70·4 vol. atmospheric air (containing 14·8 vol oxygen); but for practical purposes it is advisable to employ a dry gaseous mixture of 25 per cent. SO_2 + 75 per cent. air. The dry anhydride does not attack cast or tinned iron. In some works in Russia and Germany this process is actually carried out on a commercial scale with some modifications and improvements on the old idea.

In Kalk, near Köln (Cologne), in Germany, Wolter's process is used by distilling hydric sodic sulphate: $2NaHSO_4 = Na_2SO_4 + SO_3 + H_2O$. The sulphate of soda is then treated with sulphuric acid in order to get again hydric sulphate: $Na_2SO_4 + H_2SO_4 = 2NaHSO_4$.

About five years ago a German chemist produced the fuming acid from the ordinary sulphuric acid by means of an electric current. Carbon plates about $\frac{1}{8}$in. apart are immersed in sulphuric monohydrate, and an electric current passed through the fluid. The water of the acid is decomposed into hydrogen and oxygen, and the SO_3 is absorbed by the electrolyte, thus forming fuming acid: $SO_3 + H_2SO_4 = H_2S_2O_7$. As soon as a layer of sulphur is observed on the electrodes the current is reversed. As far as the writer knows, this electrical process has never been tried on a commercial scale.—Yours, etc., R. W. HILL.

MULTIPHASED ALTERNATE-CURRENT SYSTEMS.

SIR,—With reference to your interesting leader this week, I have long thought that sufficient attention has not been paid to the lighting of many small towns in the mountainous parts of this country. At the same time there are serious difficulties in the way. In most of the smaller towns there is not sufficient money to establish a local company or district council works, whilst the return would be hardly sufficient to induce outsiders to invest in such work.

Beyond this, there are the Board of Trade regulations to consider, and unless the Board relaxes the regulations as to constant supply at a given pressure and as to overhead lines, it would in many cases that I have in my mind be almost impossible for a company to make a living. In most cases overhead wires would be imperative except in the centre of the town.

Further than this, it must not be forgotten that a mountain torrent usually varies enormously in volume, so that unless considerable expense is incurred for storage the minimum is not sufficient for the load, in which case coal has to be carted. Added to this is the fact that most of the suitable water rights are already occupied, and that in very few towns is there water power available in the town itself, but more often some distance off.

In most such towns, also, the hydraulic machinery is unsuitable for the use of electric lighting, either being wasteful of water or taking up too much space. At the same time, I think more use might often be made of water power than at present is the case.—Yours, etc.,

Littlehampton, August 2, 1895. GEO. T. PARDOE.

NORTH-WESTERN FEVER HOSPITAL.

The following report on the tenders for electric lighting has been submitted to the Metropolitan Asylums Board by Prof. W. E. Ayrton:

"Until comparatively recently the recognised method of running electric wires in buildings was to place them in wooden casing, the capping of which had to be removed both to put in the wires and to inspect them. Although this system

Digitized by Google

found favour with the fire insurance companies, gradually people realised that it possessed many serious defects, and so conduit systems began to be developed. With these, pipes made of either bitumenised paper, earthenware, iron, steel, or zinc are embedded in the walls during the construction of the building, and subsequently the going and return conductors are drawn into these pipes or drawn out again without disturbing the walls should the conductors at any time become defective. When, therefore, it was decided to electrically light the new isolation block and pavilions, I applied to the Westminster Insurance Office for permission to use such a conduit system. Their surveyor of risks admitted the force of my arguments in favour of a conduit; but, as he had to obtain the consent of several insurance companies, who share the North-Western Hospital fire risk, it was not until I had had several interviews that he gave his consent, which was coupled, however, with a statement of his preference for a *non*-metallic tube. Under these circumstances, and especially as the details of several of the conduit systems are covered by patents, and therefore can only be used with the permission of the holder of the patent, I considered it undesirable to specify the material of the conduit with the minuteness with which I had described the other details in the specification for the wiring of the isolation block and pavilions. And further, to enable any firm to tender that was prepared to employ a conduit system, as distinguished from the old-fashioned wooden casing, I specified: '*Samples of the conduit which the contractor proposes to use for protecting the conductors from abrasion, vermin, damp, etc., must be sent with the tender.*' Appended is a list of the tenders, arranged in increasing order of price, and attached to each is a description of the material proposed to be used for the pipe:

Name of firm.	Amount of tender.	Material of Conduit.					
		Bitumenised paper.		Earthenware.	Iron.	Steel.	Zinc.

"After a careful survey of the 17 tenders, and of the samples accompanying them, I am of opinion, for the following reasons, that the Board will receive the best value for their money by accepting the tender of Messrs. Fowler, Lancaster, and Co. for £859. 15s.:

"(i.) Zinc tubes, such as those proposed by Messrs. Fowler, Lancaster, and Co., are much stronger than those made of bitumenised paper, and will stand the action of damp and of cements better than paper.

"(ii.) Zinc is stronger than earthenware unless the latter be very thick; further, zinc tubes can be obtained in greater lengths, and also can be joined together more easily, than earthenware tubes. Therefore, zinc is to be preferred to earthenware for mechanical reasons, and, when insulated wire of the class stated in the specification is employed, no electrical advantage is practically gained by using a tube composed of non-conducting material.

"(iii.) As Messrs. Fowler-Lancaster are prepared to use steel tube where, in my opinion, there is a special risk of mechanical injury, their system is nearly as good as one in which iron pipes are used throughout.

"(iv.) The tender of Messrs. Fowler-Lancaster is nearly £200 less than the lowest of those in which iron pipes are quoted for, and only £300 more than the lowest tender of all. And as this latter is for a simple paper-tube system, I do not recommend its adoption.

"(v.) As Messrs. Fowler-Lancaster's zinc tubes are made out of *rolled sheet*, and as the steel tubes they use are *smooth inside*, there is far less risk of damage to the insulation of the conductors in drawing in than if rough gas barrel were employed, as is contemplated in some of the higher tenders.

"(vi.) Lastly, Messrs. Fowler-Lancaster have good testimonials for the success they have obtained in the use of their zinc tubes.

"I therefore recommend that the tender of Messrs. Fowler, Lancaster, and Co., for £859. 15s., be accepted. Finally, I would suggest that the Board having received a tender which is only fifth from the lowest, for a combination system of special zinc tube and smooth steel pipe, furnishes a conclusive proof of the advantage that the Board has derived from the material of the conduit having been left open in the specification."

[And Messrs. Fowler, Lancaster, and Co.'s tender has been accepted according to the report—the statement in our issue of July 26 that the lowest tender was accepted, being, we regret to say, inadvertently and unfortunately incorrect.—Ed. *E. E.*]

LIVERPOOL CORPORATION AND ELECTRIC LIGHTING.

DETAILS OF THE SCHEME OF PURCHASE.

We herewith give the full text of the report which the chairman of the Lighting Committee of the City Council (Alderman Frederick Smith) has prepared with regard to the purchase of the business of the Liverpool Electric Supply Company, Limited:

It will be within the recollection of the Council that, by the Liverpool Electric Lighting Order, 1892, the Corporation obtained power to purchase, as a going concern, the portion of the undertaking of the Liverpool Electric Supply Company, Limited, within the city of Liverpool, on giving not less than 12 months' notice prior to June 30, 1898, or on any subsequent June 30. The earliest date for purchase fixed by the order of 1892—namely, in the year 1898—was, by arrangement made with the company during the enquiry on the question of the extension of the city boundaries, extended to the year 1900, on condition

Digitized by Google

that the company gave the Corporation power to buy that portion of their undertaking in Toxteth Park, as well as the portion in the existing city. Soon after the committee were appointed in November, 1894, they approached the directors of the company with the view of ascertaining whether the directors would be willing to negotiate for the purchase of the undertaking by the Corporation in the year 1895, instead of waiting until the year 1900, and the directors intimated that they were prepared to negotiate, provided the committee had authority from the Council to complete the bargain, if the terms could be mutually agreed upon. The committee consequently recommended the Council to give them that authority, and on January 9, 1895, the Council passed the following resolution: "That the Council offer to purchase from the Liverpool Electric Supply Company, Limited, the whole undertaking and business of the company, as a going concern, during the year 1895 (instead of waiting until the period arrives when the Corporation can compel the company to sell their undertaking, as a going concern), at such price and on such other terms and conditions as may be agreed upon between the company and the Special Lighting Committee, or, failing such agreement, as may be settled by arbitration in manner provided by the Liverpool Electric Lighting Order, 1892, and that the Special Lighting Committee be authorised to take all steps, and to do whatever may be necessary, to carry out the object of this resolution, and that the Lord Mayor be respectfully requested to affix the corporate seal to any document that may be necessary." In accordance with that resolution, the committee entered into negotiations with the directors of the company, and arranged, provisionally, the terms of purchase, subject to the undertaking being examined by an expert and to his report being a favourable one. The committee thereupon called in Sir Frederick Bramwell to examine the whole of the machinery and works of the company, and to report. In a lengthy report describing the character of the works, Sir Frederick Bramwell concluded with the following remarks: "As a summary, and in conclusion, I am of opinion that the Corporation, in acquiring the undertaking of the Liverpool Electric Supply Company, will become possessed of a means of generating and distributing electrical energy which has been well designed, has been well carried out, has been maintained in admirable condition, and has worked, and will continue to work, with an economy that, so far as I know, has never been surpassed."

After this report was received, the committee agreed that the Corporation should purchase the undertaking on the terms set out in the following agreement:

"An agreement, made the 28th day of May, 1895, between the Liverpool Electric Supply Company, Limited (hereinafter called 'the company'), of the one part, and the Mayor, Aldermen, and Citizens of the city of Liverpool (hereinafter called 'the Corporation') of the other part. (1) The company agree to sell, and the Corporation agree to purchase, for the sum of £400,000, the whole of the undertaking and other works of the company, and all their property and assets, real and personal (except as hereinafter mentioned), with all their rights, powers, and privileges, subject to all enactments, contracts, obligations, rights, and liabilities affecting the same at the date of completion of the purchase, but subject to the provisions hereinafter contained and excepting out of the said purchase: (*a*) The reserve and renewal fund of the company, amounting to £18,000, which shall continue the property of the company, to be dealt with as hereinafter mentioned. (*b*) All the minute-books, share registers, transfer-books, books of account, letter-books, and documents of the company, which shall remain the property of the company until its dissolution, after which the same (except the minute-books) shall be handed over to the Corporation, but after completion of the purchase the Corporation and their officials shall have access to the said books and documents whenever required by the Corporation. (2) The purchase shall be completed and the purchase-money paid on the 2nd day of September, 1895, or on such other date not later than the 1st January, 1896, as may be agreed upon between the company and the Corporation, or, failing agreement, as shall be settled by the Board of Trade, and if from any cause the purchase shall not have been completed by the 1st day of January, 1896, then this agreement shall be at an end, unless the Corporation and the company agree that the purchase shall be carried out at some later date. (3) The Corporation shall be liable to, and shall pay and discharge, all the debts and liabilities of every kind of the company existing on the date of completion of the purchase, including liabilities in respect of causes of action then existing and arising in connection with the carrying on of their undertaking in the usual course of business, and shall effectually indemnify the company and its directors therefrom. And the Corporation shall be entitled to all debts and sums of money then owing to the company, and the company shall, until their dissolution, allow the Corporation in the name of the company to take all such steps and proceedings at the expense of the Corporation as the Corporation may require to recover any debt or sum of money to which the company may be entitled on the date of completion of the purchase. (4) Until the actual completion of the purchase the company shall retain their present control and management of their undertaking, and shall carry on and manage the same in the ordinary and regular course of business, and from and after the date of this agreement shall carry on the same for the benefit and at the risk of the Corporation, subject as hereinafter provided, and shall also continue to keep proper accounts and may expend on capital account such sums as they think necessary for the reasonable extension of their business in order to enable them to carry out their statutory obligations or otherwise in the proper conduct of the business of the company, and may from time to time borrow such sums as may be necessary for the purposes aforesaid, but shall not after the date hereof make any other expenditure on capital account except at the request of the Corporation, provided that the provisions of this paragraph shall operate only as between the company and the Corporation, and shall not in any manner affect any other person even with notice thereof. (5) The company shall be entitled out of the receipts of the undertaking to declare and pay a dividend or dividends to their shareholders in respect to the present share capital of the company at the rate of £6 per centum per annum, free of income tax, from January 1, 1895, to the actual completion of the purchase, every such payment being made at such time and in respect of such period as the directors of the company may from time to time determine. (6) The engineer of the company (Mr. A. Bromley Holmes) and every other officer and servant of the company (but not including the directors and solicitors) who on the date of completion shall be in the employment of the company, shall (unless he signifies in writing to the Corporation that he does not desire to enter their service) be taken over by the Corporation on the same terms as to position and emoluments as those under which he was employed by the company on the 1st of January, 1895. The said engineer shall, when in the service of the Corporation, be entitled to continue to take pupils, and shall also be entitled to continue, for his own benefit, his general practice as an engineer, but not so as to prevent the efficient discharge of his duties as engineer to the undertaking hereby agreed to be sold to the Corporation. No officer or servant of the company taken over by the Corporation under this article, and signifying to the Corporation in writing within six months from such taking over that he does not desire to contribute to the superannuation fund of the Corporation, shall be under any obligation to contribute thereto, or entitled to participate therein. (7) The cost and expenses of the company in respect of the transfer of their undertaking, works, and property to the Corporation, and the winding up of the company, including the costs and expenses of this agreement and of all negotiations in connection therewith and all their costs and expenses of and incidental to the provisional order which the company have already applied for this session, and all their costs and expenses of and incidental to obtaining the ratification by Parliament of the terms of this agreement, shall be paid by the company out of their said reserve and renewal fund, and the Corporation shall not be liable to pay the same. The residue of the said fund, after payment of the cost and expenses aforesaid, shall be applied in manner following—that is to say: First, in payment of such sum or sums as the directors think fit to any officers and servants of the company (other than the directors) whose services the directors shall be of opinion have been such as to call for recognition. Secondly, in payment of the costs of winding up the company. Thirdly, in payment to the directors of the company in acknowledgment of their services of such sum as the shareholders in general meeting may determine, and the balance (if any) shall form part of the assets of the company distributable among the shareholders. 8. The company will in the present session of Parliament endeavour to obtain the confirmation by Parliament, either in the said provisional order or in the Bill confirming the same, of this agreement, or of clauses comprising or carrying into effect the provisions of this agreement, and the Corporation will assist in obtaining such confirmation of the terms of this agreement by Parliament. (9) This agreement is made subject to the approval of Parliament during the present session, and to such alteration as either House of Parliament may think fit to make therein; but in the event of either House of Parliament making any material alteration therein it shall be in the option of either party to withdraw from the same, and the question whether any alteration made herein is material or not shall, if disputed, be decided by arbitration in the manner hereinafter provided. (10) This agreement is also conditional on the same being duly approved by the shareholders of the company, and is subject to a provisional order for extending the boundaries of the city of Liverpool so as to include the district of Toxteth Park being confirmed by Parliament during the present session. (11) If any dispute shall arise between the parties hereto with reference to the true construction of this agreement, or with reference to anything to be done thereunder or otherwise under or in relation thereto, such dispute shall be referred to an arbitrator, to be agreed on between the parties, or, failing agreement, to two persons (one to be appointed by

Digitized by Google

each party to the reference) or their umpire. And this shall be deemed to be a submission to arbitration within the Arbitration Act, 1889, or any statutory modification or re-enactment thereof for the time being in force, the provisions whereof shall apply so far as is applicable. In witness whereof the company and the Corporation have hereunto affixed their respective seals the day and year first before written.

It will be seen that the purchase is to include, not only the company's undertaking in the city, but that within Toxteth Park also. In order to carry out the agreement for the purchase, it is necessary that parliamentary sanction be obtained. The committee thought it possible that the terms of the agreement might have been included in a Bill to confirm the provisional order which the company are promoting during the present session, but the authorities of the House of Lords, after a good deal of consideration, decided that as a matter of procedure it would be necessary for the company to promote a separate Bill to carry out the agreement, and to authorise the Corporation to borrow the necessary capital to pay for the undertaking. The committee have arranged with the company to take this course, and it has been agreed that one-half of the taxed costs of the Bill shall be paid by the directors out of the reserve fund, and the other half out of the ordinary assets of the company. The purchase will be dependent on the extension of the city boundaries being carried out.

The total sum required to be borrowed by the Corporation will have to be repaid within a period to be fixed by the Local Government Board after the Act to authorise the purchase has been obtained. In the case of the London County Council the Treasury have within the last 12 months adopted a period of 42 years for electric lighting purposes, and there is no reason why the Local Government Board should not adopt the same period. Calculating interest at 2¾ per cent. (to be on the safe side), and assuming a period of 42 years is allowed for repayment, and calculating the total capital required by the date when the purchase will be completed at £425,000, the annual charge to the Corporation for interest and sinking fund will be £17,187. If a period of 35 years is taken, the annual charge would be £19,064. As against this annual charge, the Corporation will have an undertaking which for the year 1894 produced a net revenue of £20,908 after payment of working expenses, maintenance, and directors' fees and legal charges. The directors' fees and solicitors' charges amounted in 1894 to between £900 and £1,000, and as these charges will not be payable if the Corporation purchase the undertaking, the net revenue for the year, from a Corporation point of view, may be taken at £21,800. During the first six months of the present year there has been a considerable increase in the business of the company, the gross receipts from the sale of electricity showing an increase of £2,500 on the receipts for the corresponding period of last year.

The following table shows the development of the undertaking during the last five years :

Year.	Number of lamps on December 31.	Sales of electricity.	Profit before deducting depreciation.
1890	11,752	£13.343	£7,792
1891	14,966	20,123	11,760
1892	20 254	25,515	16,751
1893	25,784	27,258	17,507
1894	31,792	31,352	20,908

During the first six months of 1895 the number of lamps has increased from 31,792 to 33,800. It is, therefore, reasonable to calculate that the net income from the undertaking for 1895 will be between £23,000 and £24,000, as against an annual expenditure by the Corporation of £17,187 if 42 years for repayment of the borrowed money is allowed, and as against £19,064 if 35 years is allowed. When the Corporation acquire the undertaking they will be able to increase the gross receipts in a short time by between £3,000 and £4,000 per annum by lighting the public buildings in the centre of the city with electricity instead of gas. This can be done almost entirely from the existing mains of the company, and only a small capital expenditure will be necessary to carry it out. The amount paid to the gas company in 1894 for gas supplied to all the public buildings was £7,065. 2s. 10d., and the amount paid in respect of those buildings in the centre of the city which could easily be lighted by electricity was £3,486. 16s. 7d. In addition to this, the Corporation will be in the position to consider the question of lighting the chief streets with electric light instead of gas, and of supplying electricity for motive power. The share capital of the company consists of 50,000 £5 shares, and the company had spent additional capital on the works to the extent of about £16,000 up to May 31, 1895. Since July 1, 1894, the company have paid a 6 per cent. dividend, and by their provisional order of 1891 they can pay a dividend up to 7 per cent., but after that point has been reached one-half of the surplus profit must be applied in the reduction of charges, and the other half can be paid as additional dividend. By the purchase of the undertaking the Corporation will get the right of supplying the city with electricity into their own hands at a price which is undoubtedly a good one for the company, but at the same time one which should give the Corporation, after paying interest and sinking fund, maintenance and working expenses, a considerable margin on revenue account, and there is every probability that the Corporation will be able to make substantial reductions on the present charges made by the company for electric light. In anticipation of the purchase being carried out, the committee have recommended the Council to apply next year for a provisional order to include the whole of the city, as then existing, within the area of supply.

MANCHESTER CORPORATION ELECTRIC LIGHT STATION.

The following is the report of the electric light department to the City Council for the year ended March 31, 1895 :

Your committee have pleasure in submitting to the City Council the abstract of accounts for the year ended March 31, 1895, prepared in the form prescribed by the Board of Trade, and also in reporting the following particulars as to the year's working : The number of consumers at the close of the year was 741, being an increase of 329 as compared with the previous year. The number of lamps in use was : incandescent 30,316 (of 16 c.p.), arc 385, as compared with 18,478 and 250 respectively. There were also 17 motors in use, representing 16 h.p., as compared with 11 motors, representing 16-h.p., last year. The total length of mains laid was 63 miles 258 yards. The total quantity of current accounted for was 1,199,988 units.

Revenue Account (*Abstracts* 3 *and* 4).

			£ s. d.
The amount received for sales of current, which works out to 5·63d. per unit accounted for, was...			28,145 3 6
The rental of meters was			494 19 11
Making a total revenue of			£28,640 3 5
The cost of generation, distribution, and management was	£10,991 17 4		
To which must be added—For interest, bankers' commission, and sinking fund	7,938 18 7		
For transfer to renewals account	4,000 0 0		
		22,930 15 11	
Leaving a balance of			5,709 7 6

which has been dealt with as follows :

	£ s. d.
To previous year's debit balance	209 18 10
Carried forward to next year's account (of this sum it has been decided to pay £5,140. 12s. 11d. to the city fund in aid of rates for the year ending March, 1896, as per estimates)	5,499 8 8
	£5,709 7 6

The reduction in the price of current from 8d. to 6d. per unit is estimated to affect the revenue during the current year to the amount of £4,650, but it is expected that increased business will to some extent recoup the committee for this reduction. The works reported last year to be in progress, with the new offices, workshops, and storerooms, have been completed, and are now in full use and occupancy. The following statements are appended—viz., No. 1, statement as to loans (these amount to £150,000) ; No. 2, capital account (this shows a total expenditure of £174,810, the total receipts being £150,000) ; No. 3, revenue account ; No. 4, net revenue account ; No. 5, sinking fund account (there is £4,924 carried to next year's account) ; No. 6, renewals account (£4,000) ; No. 7, general balance-sheet ; No. 8, statement of electricity generated, sold, etc. The two new 400-i.h.p. engines, with the dynamo machines and Lancashire boiler, referred to in last year's report, have been put to work. The switchboard has been extended to suit. The entire plant has worked satisfactorily, and there has been no interruption in the supply of current of more than a minute or so, and then only on a portion of the system, throughout the year. The applications for the supply of electricity have been so numerous that, as already reported to the City Council, your committee have decided to increase the plant at the central station, Dickinson-street, by the following—viz., five Lancashire boilers, 30ft. by 8ft. ; eight dynamos, each of 240-unit capacity ; six pairs of vertical compound condensing engines of 400 i.h.p. each ; two pairs of horizontal compound condensing engines of 400 i.h p each. It has also been decided to erect a storage battery at the Hunt's Bank sub-station of sufficient capacity to supply 4,000 16-c.p. incandescent lamps. It has also been arranged to extend the supply of electricity in and along the following streets—viz. : Oxford-street, Stretford-road, London-road and Downing-street, Port-street, Rusholme-road, Sackville-street, Chorlton-street, and Minshull-street, Swan-street (Oldham street to Shudehill), Whitworth-street, Shudehill, Withy-grove, and Fennel-street, Hunt's Bank. The Local Government Board have given power and authority to the Corporation to borrow the sum of £100,000 for carrying out the foregoing extensions and increase of plant, which are expected to be partly available for the ensuing winter of 1895-6. The plans for these extensions are in a forward state, and main-laying has already been begun. The method of distribution will be as before—on the five-wire system ; and it is intended to carry out the extensions of mains by the Corporation's own staff.

LEGAL INTELLIGENCE.

THE BOARD OF WORKS FOR THE WANDSWORTH DISTRICT v. THE COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

This case came before Mr. Justice Stirling in the Chancery Division of the High Court of Justice on Saturday last. It was a motion by the plaintiffs asking that the defendants, their servants and agents, might be restrained by injunction from excavating, or constructing, or placing in or under any highway within the plaintiffs' district any transforming or converting stations or other chambers or receptacles for the purpose of containing transformers or other apparatus for the purpose of transforming or converting electrical energy at a high pressure to energy at a low pressure, and from constructing or placing in or under any such highway any other chambers or stations not being street boxes authorised by Clause 12 of the provisional order granted by the Board of Trade in respect of Wandsworth, and scheduled to the Electric Lighting Orders Confirmation (No. 5) Act, 1892, and from using any boxes constructed by the defendants under the powers of the said Act for the purpose of transforming electrical energy as aforesaid, or for any other purpose not authorised by the said Clause 12. The question raised in the action was of considerable importance to public authorities and electric lighting companies—viz, whether, under the terms of the provisional order which authorised the placing of "boxes" under the streets for certain purposes therein specified, the defendant company were at liberty to construct chambers of considerable size under the streets of the plaintiffs' district for the purpose of containing apparatus to be used in converting or transforming electrical energy from high pressure to low. Section 9 of the provisional order referred to provided that the undertakers might supply energy within their area by means of some system to be approved by the Board of Trade, and subject to such regulations for securing the safety of the public as the Board of Trade might impose. Section 11 gave the undertakers certain powers to break up streets, etc, for the purpose of executing their works. Section 12 provided as follows: "Subject to the provisions of this order and the principal Act, and any regulations made under this order, the undertakers may construct in any street such boxes as may be necessary for purposes in connection with the supply of energy, including apparatus for the proper ventilation of such boxes, provided that no such box or apparatus shall be placed above ground except with the consent of the local authority, or person by whom such street is repairable. Every such box shall be for the exclusive use of the undertakers and under their sole control, except so far as the Board of Trade may otherwise order, and shall be used by the undertakers only for the purpose of leading off service lines and other distributing conductors, or for examining, testing, regulating, measuring, directing, or controlling the supply of energy, or for examining or testing the condition of the

Digitized by Google

mains or other portions of the works, or for other like purposes connected with the undertaking; and the undertakers may place therein meters, switches, and any other suitable and proper apparatus for any of the above purposes."

The plans of the defendant company had been sanctioned by the Board of Trade, and included the construction of cast-iron receptacles to be placed under the streets The dimensions of the receptacles so authorised were 10ft. in depth, 7ft. 6in. in length, and 5ft. 6in. in width. and they were intended to contain instruments called transformers or converters. A transformer is an apparatus through which the electric current is passed with the view of changing or controlling its voltage. It consists of a mass of iron, round which are wound the primary and secondary conductors without being brought into contact, and according to the number of times the respective conductors are wound round the iron so is the pressure of the electrical energy diminished. In this way the current is rendered capable of being taken off the electric main and conducted at a safe pressure into the consumers' houses. The case of the plaintiff Board of Works was that the receptacles or chambers proposed to be used by the company were not street "boxes" within the meaning of the Electric Lighting Acts and the provisional order, and that, even if they were, the use of them for the purpose of transforming was not within the uses prescribed for such boxes by the order. They contended that it would be extremely inconvenient for public purposes if these large spaces were permitted to be taken up under the streets, and that, having regard to the safety of the public, it was not desirable that what was proposed should be done. "Transforming" was a well-known operation applied to electricity, and if it had been intended that the process of transforming should be allowed in these boxes, the word would have been expressly inserted in the order. The defendants, on the other hand, contended that the Legislature had used terms of the widest possible signification, and that their proposed operations were entirely within their powers.

Mr. Justice Stirling, in giving judgment, said that the question was really one of construction of the order which was granted by the Board of Trade and confirmed by Parliament, and which had all the efficacy of an Act of Parliament. After referring to the scheme of the order, his Lordship said that it was obvious that great powers were vested in the Board of Trade. First of all, the system of electric lighting was to be that which had met with the approval of the Board of Trade, and it was only to be used subject to such regulations as might be imposed by that body; and, secondly, where the operations of the undertakers involved the placing of works under, along, or across any street, the undertakers were to furnish details of what was proposed to be done to three bodies—viz, the Postmaster General, the local authority, and the County Council—and it was left to those bodies to approve or disapprove the plans; in the event of their being disapproved the undertakers might appeal to the Board of Trade, who had the function of adjudicating between the undertakers on the one hand and the three public bodies on the other. All that had been done in the present case. The Board of Trade had fixed upon the system to be adopted. They had defined it in the following manner: "A high-pressure alternating-current supply at constant pressure to transformers, which will be placed either in converting stations or, when the houses or buildings to be supplied are widely separated, on the consumer's premises. From the converting stations a low-pressure supply at constant pressure will be given to consumers by means of distributing mains The converting stations will be street boxes of sufficient size and suitable construction to contain several transformers, room being also provided to enable a man to enter the box and conveniently examine the transformers and controlling apparatus." According to the plans of the defendant company, the street boxes which were intended to be used, and which had been sanctioned by the Board of Trade, were receptacles made of iron, of which the dimensions were 10ft. in depth, 7ft. 6in. in length, and 5ft. 6in in width, and they were to be used for the purpose of containing the transformers which were to change the electricity from high to low pressure. The objection raised by the Wandsworth Board of Works was that the Board of Trade, in sanctioning these receptacles, had authorised something which, according to the terms of the order, the defendants were not entitled to use. That turned upon the construction of Clause 12. The notice of motion raised two points—first, that the receptacles were not "boxes" under the section; and, secondly, that the use of them for the purpose of containing the transformers was not properly sanctioned. His Lordship dealt with these questions separately. First, were the receptacles "boxes" within the Act? The "boxes" in common use at the time of the passing of the order were of much smaller dimensions than those now proposed to be used. But there was nothing in the Act as to size; and it seemed to his Lordship that the question of size was entirely within the province of the Board of Trade. Then it was said that the receptacles were really chambers and were so designated in the first plans put forward by the company; but the question was whether they might be described as "boxes." His Lordship thought that they might fairly be so described, and the Board of Trade had not gone beyond their powers in sanctioning them. Secondly, might they be used for the purpose of containing the transformers? The uses to be made of "boxes" were defined in the latter part of Clause 12—viz. (*inter alia*), for "regulating, measuring, directing, or controlling the supply of energy." It was not disputed that if the boxes might be used for transformers, the instruments themselves were such as might be properly used. But it was said that none of the words in the order described the function to which the transformers were appropriated. On the other hand, it was said by the company that the transformers were apparatus for regulating or controlling the energy. Their effect was to diminish the pressure in a certain fixed ratio depending upon certain conditions; and his Lordship came to the conclusion that the operation clearly came within the words "regulating and controlling," and the Board of Trade had not gone beyond their powers in sanctioning the use of these instruments in the "boxes." The motion was accordingly refused, and, by consent, the hearing was treated as the trial of the action, and the action was dismissed, with costs.—*The Times.*

WILSON v. THE ELECTRICAL COMPANY, LIMITED.

In this case, which was heard in the Court of Queen's Bench on Tuesday, defendants applied that the plaintiff's action be dismissed for want of prosecution, the plaintiff not having filed answers to interrogatories delivered pursuant to order made herein on July 6, 1895, without prejudice to the right of the defendants, the Electrical Company, Limited, to proceed with their counterclaim. The plaintiff, Mr. G. S. Wilson, now stated to be of the Zürich Incandescence Lamp Company, formerly in the employ of the defendants as traveller, applied for an extension of time in which to answer the above-named interrogatories. The plaintiff brings an action for damages against the defendants in connection with an alleged illegal acting upon an alleged invalid bill of sale.

The plaintiff was granted 10 days within which to answer the interrogatories.

COMPANIES' MEETINGS AND REPORTS.

WATERLOO AND CITY RAILWAY COMPANY.

The third half-yearly meeting of the above Company was held at Waterloo Station yesterday (Thursday) afternoon, Mr. Wyndham S. Portal in the chair.

The **Chairman** moved the adoption of the report of the directors and statement of accounts, which showed that the expenditure for the half-year ended June 30 amounted to £48,982. The probable further outlay within the current half-year rendered it necessary to make a call of £2 per share upon the 54,000 shares of the Company. The total capital created is £540,000. The general balance-sheet shows on the debit side, balance at credit of capital account, £80,085. 4s. 9d; interest accrued and provided for, £1,565. 10s. 1d.; and sundry outstanding accounts. £224. 12s. 5d.; and the credit side, cash at bankers, £6,775. 7s. 3d; cash on deposit at interest, £50,000; cash invested in Consols for parliamentary deposit, £25,000; and outstanding accounts, £100; total, £81,875. 7s. 3d. The chairman said that since they had met six months ago they had been actively engaged in continuing the work of the railway, and consequently there had been a considerable increase in the outlay of capital as compared with the previous half-year. The present rate of progress was satisfactory in all respects. There was, however, an interval of several weeks, when operations were wholly suspended on account of the severe frost. Good progress had been made with the tunnels, which had been driven entirely underneath the bed of the Thames, and for a length of 300 yards on the Surrey side and 120 yards on the Middlesex side of the river. Up to the 30th June 1,200 yards of single tunnel had been constructed. Towards Waterloo one tunnel was entirely in clay, but the down tunnel had at one place touched gravel. The compressed air, however, kept the water back. Water would also be touched nearer Waterloo, but the engineers were prepared for this. No damage whatever to buildings had been traced during the operations. Two electric locomotives were at work in the tunnels. There was a delay of about a week owing to the requirements of the District Railway Company, but this matter had been settled satisfactorily. With respect to terminal stations negotiations had been completed with the London and South-Western Railway Company for the Waterloo end, and negotiations with the City and South London Railway Company for the City station were in a forward state. All calls had been duly received, and the number of shareholders was now 541, against 494 at the last meeting. He congratulated the shareholders, engineers and contractors on the comparatively few difficulties which had been met with.

Lieutenant-Colonel the Hon. H. W. Campbell seconded the motion, which was adopted.

CROMPTON AND CO., LIMITED.

Directors: The Viscount Emlyn (chairman); Rookes Evelyn Bell Crompton, Esq., John Francis Albright. Esq (managing directors); Bernard Gibson, Esq.; Carleton F. Tufnell, Esq.

Seventh report of the directors, to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon-street, E.C., on Friday, August 9, 1895, at 3 p.m:

The directors beg to report that the amount of the Company's business has again increased, but as will be seen from the accompanying statement of accounts made up to March 31 last the net profits show a considerable falling off in consequence of the further reductions in prices forced upon the Company With regard to the current year, it is satisfactory to state that the Company's order book is well filled, and the works are kept extremely busy, more so probably than at any previous time. The directors consider that a much healthier tone prevails in the business of electrical manufacturing, and they hope that there will now be a steady advance to better prices and better profits. The new debentures offered for subscription in January last were subscribed for to the amount of £82,850, which has provided additional working capital, and

Digitized by Google

enabled the Company to materially reduce the bankers' loans. With regard to the cooking and heating department of the Company the directors are pleased to report that they have, since March 31, granted a license for the manufacture and sale of these appliances in France, the Company receiving £1,000 for the privilege and a substantial royalty on all sales. Negotiations are also in progress for granting licenses for other foreign countries. The net profits for the year amount to £6 953. 10s. 11d., and after providing for debenture interest and other payments there remains a net revenue balance of £2,343 15s. 9d , from which the directors propose to set aside £1,000 for contingencies and doubtful debts, and to carry the balance, £1,343. 15s. 9d.. forward. They further propose to transfer the sum of £1,000 from the reserve fund in reduction of the preliminary expenses account The seven years fixed by the purchase agreement of July 16, 1888, during which the Company secured the right to the services of Mr. R. E. Crompton and Mr. J. F. Albright as managing directors having expired, the Board have made arrangements for a continuance of their services. The directors regret to state that, in consequence of his having entered into other business engagements which necessitate his residing a long distance from London, Mr. H. H. J. W. Drummond has resigned his seat on the Board of the Company. In accordance with the articles of association, Mr. Bernard Gibson retires from the Board of Directors by rotation, but offers himself for re-election. The auditors, Messrs J. H. Duncan and Co., also offer themselves for re-election.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY, LIMITED.

The report of the directors for the half-year ended June 30 states that the gross receipts for the half-year amount to £42,820, and the working and general expenses and renewals are £33,177, leaving a net balance of £9,643, and it is proposed to pay a dividend at the rate of 6 per cent. per annum, free of income tax, for the half-year, carrying a balance of £2,415 to reserve and renewal funds. The investments which appear in the balance-sheet at cost price of £23,934 are at to-day's market value worth £25,500 The inclement weather during the early months of the half-year caused a falling off of upwards of £2,000 in the tramway traffic, but the larger portion of this was subsequently recovered, and the total decrease on the half-year amounts to £727 only. The business of the carriage department, however, shows a satisfactory increase of £787, the revenue from both departments, therefore, yielding an increase of £60. The construction of the city to Kingswood electrical line, and the conversion of the St George's depôt into a power station, are approaching completion, so that the tramway will be opened for public traffic within a few weeks.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Torrevieja.—Tenders are invited by August 20 by the municipal authorities of Torrevieja, Alicante, Spain, for the concession of the electric lighting of the town. The annual rental named is 4,000 pesetas for 100 16-c.p. incandescent and three 400-c.p. arc lamps.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895 for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Portsmouth.—Tenders are invited for laying about seven miles of stoneware ducts for electric cables required for the extension of the Corporation system. Specifications can be obtained at the station, Gunwharf-road, and tenders, addressed to the chairman of the Electric Lighting Committee, should be delivered there by 14th inst.

Berlin.—Tenders are invited for the supply of boilers for electric central stations of largest proportions, meeting the following requirements; high-pressure, very dry steam, minimum floor space, adjusting themselves to greatly variable steam consumption, easy cleaning, highest economy and efficiency, greatest possible safety against breakdowns. Apply to Allgemeine Elektricitäts-Gesellschaft, Schiffbauerdamm 22, Berlin, N.W., Germany.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep burning at the same time 2,200 8 c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, on or after July 10, 1895, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Sunderland.—The Corporation invite tenders for (*a*) high-tension and low-tension concentric cables; (*b*) cast-iron pipes and box frames and covers; (*c*) stoneware casing, boxes, and bell-mouth protectors; (*d*) high tension transformers for alternating current; (*e*) meters for alternating current. Specification, etc., can be obtained on payment of one guinea at the office of the borough electrical engineer, Electric Supply Station, Sunderland, on and after Monday next. The deposit will be refunded on receipt of the specification and conditions of contract with a *bonâ fide* tender. Tenders should be delivered at the town clerk's office by Monday, 26th inst.

Killarney.—The Commissioners for the Control of Lunatic Asylums, Custom House, Dublin, invite tenders for the electric

Digitized by Google

wiring of the Killarney District Lunatic Asylum, the same to be connected to the supply mains (high tension) of the Killarney Electric Lighting Company. Forms of tender will be issued on application to the above Commissioners on deposit of £1, which will be returned to all persons who have sent in *bonâ fide* tenders on return of specification. The plans and specification can be seen at the asylum or at the office of the engineer, W. Leake, Esq., 30, Victoria-buildings, Manchester. Tenders are to be sent in by 30th inst.

Islington.—The Vestry are open to receive tenders for the wiring of the Vestry Hall and municipal offices in Upper-street, N., and for the supply of fittings. Specification, etc., can be obtained on application to the electrical engineer, Electricity Department, 50, Eden-grove, Holloway, N., after the 13th inst. Deposit of £1. 1s. will be required for the forms, but such deposit will be returned on receipt of a *bonâ fide* tender. The contractor whose tender is accepted will be required to pay his employés engaged on the work the trades' union rate of wages and observe trades' union conditions and hours of labour. He will also be required to enter into a contract and to find two sureties for the due execution of the work. Tenders must be sent in by 27th inst

Wakefield.—The Corporation invite tenders for the supply and erection of the following: Section A—boiler-house plant (boilers and fittings, mechanical stokers and engine economiser, feed-pump, injector, etc.); Section B—engine-house plant (steam alternators condensers, oil filter, fittings, etc, steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tank, etc.); Section C—main switchboard and instruments; Section D—underground work (cables, junction-boxes, culverts, and trenching, etc.); Section E—sub-station fittings (transformers and switchboard, etc.); Section F—arc lamps and posts; Section G—meters; and Section H—overhead crane. Particulars are obtainable from Mr. Robert Hammond, Ormond House, Great Trinity-lane, E.C., on and after August 2, on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders are to be delivered by August 24.

Blackpool.—The following has appeared in the *Blackpool Gazette*: "We hear that at Friday's meeting of the Electric Lighting and Tramways Committee that there was an important discussion on the proposal to appoint Mr. Hammond as consulting engineer for the tramway system in addition to the electric lighting works. We are informed that considerable objection was raised to this appointment, and we hope that the strongest reasons will be demanded and be forthcoming before any proposal of the sort is sanctioned by the Town Council. We are told that between March, 1894, and March, 1895, Mr. Hammond received no less than £600 in fees from the Blackpool Corporation in connection with his position as consulting engineer to the electricity works. If this is the case, we certainly think the ratepayers have every reason to object to this gentleman's powers locally being enlarged. We don't doubt Mr. Hammond's ability in the slightest, but at the same time we should like some statement from him as to whether he is responsible for the enormous expenditure on the electricity works—a matter which we claim should be fully gone into before next November. If all we hear be true, the tremendous cost of the Blackpool electricity works is a disgrace of no small magnitude to every member of the Town Council, and we shall be greatly mistaken if the ratepayers do not declare their opinion with no uncertain sound when opportunity offers. If Mr. Hammond received £600 last year he is the best paid official among the Corporation staff, and it would be interesting to know exactly how much time he devoted to the interests of the Blackpool ratepayers for this large amount. Then what are we to think about the abilities of Mr. J. Hesketh, who receives £250 per annum as electrical engineer, but whose opinion the Electric Lighting Committee evidently deem of such little worth that they require to consult Mr. Hammond so frequently as to run up fees to so large a total as £600. It seems to us that the affairs of the electricity department require overhauling from top to bottom, with a view of the ruinous expenditure of the past being accounted for, and a more business-like system adopted than having a 'consulting engineer' at £600 and an 'electrical engineer' at £250 to manage a concern of such dimensions."

RESULTS OF TENDERS.

London, W.—The St. George's, Hanover-square, Vestry have decided to light the Vestry Hall and offices by electricity, and have accepted the tender of Messrs. Strode and Co., at £278. 5s., for the work.

Aberdeen.—The Sites and Plans Committee of the Aberdeen University Court have reported the acceptance of contract for the installation of the electric light in the new halls and north block anatomical rooms, the successful offerers being Messrs. Shirres, Laing, and Co., and the estimate being £670.

London, E.C.—The following tenders have been received by the Shoreditch Vestry for the erection of a chimney shaft 150ft. high:

W. Neil, 165, Turner's-road, Bow	£3,420
Yates and Co., 223, Westferry-road, Millwall	3 270
Myles and Warner, 28. Burnard-place, Holloway, N.	3,167
Manlove, Alliott, and Co., Gracechurch-street (accepted)	2,683

London, S.W.—The General Purposes Committee of the St. James's Vestry have been considering the advisability of lighting the Town Hall by electricity, and instructed the Vestry's surveyor to bring up a specification and obtain tenders for the necessary work to be carried out. Three tenders for the work were received as follows: Freeman and Co., £39; C. J. Smith, 23, King-street, £38. 15s.; and Verity and Sons, £45. 7s. 7d. The tender of Messrs. Freeman was accepted.

Salford.—The following tenders have been received by the Salford School Board for the electric lighting of new offices. Mr. S. V. Clirehugh, A.M.I.C.E., A.I.E.E., Manchester, is the electrical engineer:

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,930.

Eastern Telegraph Company.—The receipts for the month of July were £61,413, as against £56,753 for the corresponding period of 1894.

Direct Spanish Telegraph Company.—For the month of July the receipts were £1,889, as against £1,400 for the corresponding period of 1894.

West India and Panama Telegraph Company.—The receipts for the half month ended July 31 were £1,830, as against £1,762 for the corresponding period.

Eastern Extension Telegraph Company.—For the month of July the receipts show an increase of £4,682 as compared with the corresponding period of 1894.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 4th inst. amounted to £1,355, as compared with £1,000 in the corresponding week of last year, being an increase of £355.

Aberdeen.—The Town Council have remitted to the Gas and Electric Lighting Committee for consideration a letter from the City of London Electric Lighting Company as to a proposed amendment of the Electric Lighting Acts.

Railway-Lighting.—At the half-yearly meeting of the London, Tilbury, and Southend Railway the chairman, Mr. H. Doughty Browne, said that the directors contemplated improving the lighting of the carriages by the use of the electric light.

Bradford.—At the last meeting of the Bradford Gas and Electricity Committee of the Town Council the coal contracts for the year were given out. Tenders for 129,000 tons of ordinary gas coal and also for 28,000 tons of cannel coal were accepted.

Digitized by Google

Leipzig Tramways Company.—The directors have declared an interim dividend on the ordinary and preference shares at the rate of 4½ per cent. for the half-year ended June 30.

Asbestos.—The United Asbestos Company, Limited, of Dock House, Billiter-street, London, E C., inform us that they have been awarded the contract for the supply to the Admiralty of asbestos packing and other goods for the ensuing year, 1895-6.

Church-Lighting.—Electric lighting is to be introduced into Westminster Abbey, the organ loft being treated first, at any rate experimentally. The organ-loft at Westminster Abbey is in the screen, a dark place even on the lightest days, and it is at present lit by gas.

Liverpool.—The City Council on Wednesday adopted the report of the committee who were empowered to negotiate the purchase of the undertaking and business of the Liverpool Electric Supply Company, Limited. The full report of the committee appears elsewhere in the present issue.

City and South London Railway.—The returns for the week ending August 4 were £804, compared with £849 for the corresponding period of 1894, being a decrease of £45. The total receipts for the half-year 1895 are £4,224, as compared with £4,306 for the corresponding period of 1894, being a decrease of £82.

Barmouth.—With reference to our "Business Notes" *re* Barmouth in our issues of July 26 and August 2, Mr. George T. Pardoe, Littlehampton, informs us that he had previously made proposals to the Barmouth Urban District Council with reference to electric lighting. He proposed that the Council should use water power.

House-to-House Electric Light Supply Company, Limited.—The directors of this Company have declared an interim dividend on the preference shares for the half-year ending June 30 at the rate of 7 per cent. per annum. The dividend is payable on the 26th inst. The transfer books of the Company will be closed from 16th till 26th inst, both days inclusive.

Country-House Lighting.—We understand that Messrs. Drake and Gorham have in hand a considerable amount of this class of work in the neighbourhood of Crewe. Major Kearsley, of Stapeley House, has instructed them to put down a multitubular boiler of 14 h.p. to drive a No. 6 Parker dynamo; there will be a battery of 53 cells of the D.P. Company's make.

Dewsbury.—A meeting of the Town Council was held on Tuesday, Alderman Pyrah presiding. Alderman Robinson, chairman of the Lighting Committee, reported a large increase in the consumption of gas, despite the extending use of the electric light, as supplied by the Corporation, and this was regarded as very satisfactory. Both these facts told of the prosperity of the town, which he hoped would long continue.

Portsmouth.—The Roads and Works Committee of the Portsmouth Town Council have deputed their chairman and vice-chairman to accompany Mr. A. W. White to Bristol to inspect the works connected with the establishment of an electric tramway at that place. This proceeding has been taken in view of a proposal to utilise the current now generated at the borough electric lighting station in the daytime to propel the cars on the Lake-road line, when the tramway is relaid on the completion of the drainage works now in progress.

Aberystwith.—A meeting of the Public Lights Committee of the Corporation has been held, when it was agreed to recommend the Council to remove the electric lamp in Great Darkgate-street which at present lights Market-street. It was decided to ask the electric light company if they would modify their charge per lamp for the use of an extra six lamps during the months of July, August, and September. The committee also decided to report to the Council that it was agreed to defer the question of placing two lamps on the Penparke-road for a couple of months.

Longton.—At the last meeting of the Town Council a draft agreement between the North Staffordshire Tramways Company and the Corporation with reference to the alteration of the date upon which the Corporation can compulsorily purchase the tramways in the borough from eight years to 22 years, and to sanctioning the working of the tramways by electricity by means of overhead wires, was read by the town clerk. It was stated that the same agreement was being submitted to the other local authorities in the district. On the motion of Mr. Brookfield, the agreement was approved.

Glasgow.—A meeting of the Town Council was held on Thursday last week, at which Councillor Mitchell, the new convener of the Gas Committee, submitted the annual report on gas supply and electric lighting. In the electrical department the committee regretted that a profit had not yet resulted. No doubt this state of matters would be altered in the near future, and the plant at Waterloo-street and John-street was expected to be fully occupied during the coming season. Meantime, the committee did not propose to alter the price of 6d. per Board of Trade unit, at which electricity was at present supplied. The report was adopted.

St. Helens.—At a meeting of the Electric Lighting Committee of the St. Helens Corporation the following tenders for the supply of the plant for providing electric lighting in the borough were accepted, subject to the approval of the Local Government Board: boiler-house plant, Yates and Thom; engine house plant, Johnson and Phillips; switchboards, S Z de Ferranti; underground work, British Insulated Wire Company; transformers, John Fowler and Co.; meters, Chamberlain and Hookham; travelling crane, Carrick and Ritchie. The committee instructed the town clerk to apply to the Local Government Board for sanction to borrow £10,000 for carrying out the works in question.

Tunbridge Wells.—At Wednesday's meeting of the Town Council, the Town Clerk reported to the Lighting Committee that he had received from Mr. Preece a plan showing the positions of the mains to be laid on the Pantiles as finally decided upon, and had forwarded the same to Messrs. Burn and Berridge on behalf of the lady of the manor, at the same time stating that the plan was submitted without prejudice. It was resolved to instruct the engineer to proceed with the works on hearing from Messrs. Burn and Berridge, and also to proceed with the construction of the transformer-chamber between the Pantiles and the Pump-room.

I E S Accumulator Company, Limited.—This Company has been registered by J. L Higgs, 43, Finsbury-square, E.C., with a capital of £100,000, to carry on business as manufacturers of and dealers in electric storage batteries; as electrical engineers and electricians, mechanical engineers, producers and suppliers of electricity for light, heat, or motive power; as manufacturers of and dealers in electrical apparatus and appliances; to supply accumulators for the purpose of lighting omnibuses, tramcars, cabs, and other vehicles, public or private buildings, manufactories, mines, ships, lighthouses, railways, etc.; to establish and maintain telegraph, telephones, electric bells, phonographs, etc.

Southborough.—At the last meeting of the Urban District Council the clerk read a letter from the Guildford Electricity Supply Company, Limited, of 34, Victoria-street, Westminster, who gave notice that they intended to make application, on or before December 31, by memorial to the Board of Trade, in pursuance of the Electric Lighting Acts, 1882 1888, for a provisional order, to be confirmed in Parliament in the ensuing session, whereby they might supply electricity for public or private purposes within the area of the Southborough Local Authority. The Chairman stated they had a similar communication last year, and they opposed the proposal. They would oppose the application at the proper time.

Ipswich.—At Friday's meeting of the Lighting Committee of the Town Council, the Town Clerk said he had received a formal notice that the County of London Brush Electric Lighting Company, Limited, intended before December 21 to apply for an electric lighting order for Ipswich. The Chairman supposed the only thing the committee had to do was to report the fact to the Council. The Town Clerk said there would be time enough when the company made the formal application for the order. In many cases this notice was given and the matter went no further. Mr. Josselyn observed that no authority had been given by the Council to the committee in reference to electric lighting. The matter then dropped.

Copper.—Messrs. Henry R Merton and Co's copper statistics show that the visible supply was slightly smaller at the end of July than a month previously. The total stocks in England and France and afloat now amount to 57,817 tons, against 58,182 tons on June 30, the deliveries during the past month having exceeded the supplies by 365 tons. The satisfactory feature in the case, which points to higher prices for copper, is the fact that the excess of deliveries was, in spite of arrivals from the United States, larger than in any month since December, 1893. Should the supplies from the United States decline during the next few months, as is expected in well-informed quarters, there will certainly be a further substantial advance both in the metal and the shares of copper companies.

Leeds.—The Yorkshire House-to-House Electricity Company are about to make a large extension of their mains, by which the electric light will be brought within reach of the residents of Chapeltown and the occupiers of business and other premises along the important thoroughfares *en route*. The existing mains terminate in New Briggate, and it is now intended to carry them along North-street and Chapeltown-road and Harrogate-road, as far as the tram terminus. The necessary preparations having been made and plans deposited, the work will be put in hand almost immediately, and it is expected that the supply of current will be available at an early period of the autumn. Already a considerable number of residences and business establishments are being fitted up to receive the light.

Mersey Railway Company.—The report of the directors of this Company states that after the date of the last half-yearly meeting the directors made a further enquiry into the important matter of working the railway by electricity, or other motive power, and decided to proceed with the Company's Bill in Parliament for the necessary powers. The Bill has passed the committee of the First House. Owing to the unfavourable response of the debenture stockholders and the proprietors in regard to raising £50,000 further capital and to the "scheme," the clauses in the Bill relating thereto were withdrawn. Valuable as the Bill may prove to be, the directors remind the shareholders and the debenture stockholders of the great necessity for a scheme, either in Chancery or under Act of Parliament, being agreed upon, so that money may be raised when necessary as cheaply as possible.

Ossett.—A meeting of the Town Council has been held at which a resolution was passed in favour of the promotion of a Bill for the purchase of the undertaking of the Ossett Gas Company. Councillor Lucas said that a scientific gentleman (?) had told him it would be very unwise to purchase the gasworks, and that the electric light six months hence would be quite a different thing to the electric light of to-day. Alderman Mitchell, however, did not fear that gas would be superseded. It was a very useful commodity, and when the electric light was perfected as far as it could possibly be, there would still be room for gas and electric light. Councillor Phillips did not think there would be a larger consumption of gas, because electric light was making rapid strides. Alderman Lucas considered that electric light was the light of the future, even in

Digitized by Google

Ossett, and the use of the electric light must curtail the consumption of gas.

Acton.—At the last meeting of the District Council it was reported that the Capital and Counties Electricity Supply Company had acknowledged the receipt of the clerk's letter, stating that the Council would oppose their application to the Board of Trade for a provisional order empowering them to supply electric light and power in Acton. A letter was also read from the City of London Electric Lighting Company suggesting that the Council, as the undertakers under an electric lighting provisional order, should co operate in an endeavour to alter the existing law in a respect in which it operated harshly towards such undertakers. The communication was referred to the Works Committee without comment upon its subject. Mr. Terriss, of Bedford-park, having written asking when electric light would be available in the parish, the Works Committee recommended that he be informed that there was no immediate prospect of electric light being brought into the district

Wimbledon.—At the Urban District Council's meeting on the 31st ult. the Lighting Committee recommended the adoption of Mr. Arthur Preece's electric lighting scheme, which we give *in extenso* in another column and that the Local Government Board be asked to sanction a loan of £32,000 to carry out the same The Chairman said the working expenses were estimated at £2,475 per annum and the interest and repayment on the loan £1 700, making the total liabilities over £4,175 per annum. As a set-off to that there was the cost of lighting the public lamps with oil (£1,800), meter rents were estimated to produce £75, and if the public would take 3,500 lamps at 10s. each it would leave an apparent deficiency of £550. Mr. Preece had not, however, taken into account the £150 which the Council at present paid for their office, etc., and which, perhaps, would be included in the private lighting estimates. Mr. Preece considered the response of householders very satisfactory. The recommendation was adopted unanimously.

St. Pancras.—The Vestry have appointed Messrs. Burnett and Hooper as electricians at the King's-road station The Works Committee have brought up a report again recommending the Vestry to refuse sanction to the London Hydraulic Power Company to lay pipes in the parish. The chairman of the committee expressed himself as opposed to the recommendation, and said he understood that the Hydraulic Company was prepared to give an undertaking not to use their power to promote electricity. Mr. Sweet, the chairman of the committee, said that from the first moment that the Vestry decided to adopt electricity it was well understood they should never allow any rival competitors or any other power into St Pancras. That was the main idea which operated with the committee when the subject was first broached. They had the sole electric lighting and motive power in the parish, and they wanted to keep it. In the end the Vestry decided, by 34 to 30, to refuse the application, in accordance with the recommendation of the committee.

Gloucester.—At the last meeting of the Town Council Mr. Alderman Holtham called attention to the minute which stated that the town clerk reported that he had received from Messrs. Walter Webb and Co., London, on behalf of the Great Western Electric Light and Power Company, Limited, formal notice of their intention to apply to the Board of Trade for a provisional order to supply electricity for public purposes within the city. It would be within the recollection of the Council, Alderman Holtham remarked, that applications had been received on several occasions for the Council to supply electricity He would suggest a harmless proposition that a small committee be appointed to make the necessary arrangements so as to meet the wishes of the applicants. Mr. Councillor Clutterbuck seconded, and remarked that he considered it highly desirable to consider the matter. When the time was ripe there could be no question as to whether the people would take up electricity in the proper spirit. The Deputy-Mayor suggested that the matter should be referred back to the Finance Committee. The Mayor agreed with this proposition, and it was carried.

Croydon.—The Electric Lighting Sub-Committee of the Croydon County Council reported at the last meeting of that body that they had carefully considered the question of the exact position of the central electric lighting station. It was at first contemplated that the station should be placed upon a portion of the allotment land, but it was subsequently considered that it would be better to place the station upon the land belonging to the Corporation at Brimstone Barn. In either case it was contemplated that a siding should be constructed from the railway on to the site of the station. It appeared, however, that there would be considerable expense, and that there were other difficulties which rendered a siding impracticable. Under those circumstances the sub-committee looked about for another site, and suggested that three acres of land should be purchased in Factory-lane, nearly adjoining the Albion Works. Upon this suggestion of the sub committee the committee recommend that the land proposed be purchased at the price and upon the conditions that will be mentioned by the chairman to the Council *in camera*. The purchase-money will be provided out of the loan for which sanction has been sought.

Wrexham.—The Town Council at its last meeting received a letter from the Board of Trade with copy of an application from the Wrexham and District Electric Supply Company, Limited, applying for a further extension of time, and stating that, subject to any observations which the Corporation might wish to offer, the Board of Trade proposed to defer consideration of the question of the revocation of the order for a further period of six months from August 15. Alderman Bevan moved and Mr. Charles Davies seconded that the Council offer no objection to the course which the Board of Trade proposed to take. Mr. Thomas Jones thought the time had come when the Council should put a limit to such applications. He understood that the company had not paid the £500 required, and that some of the shareholders were refusing to pay calls, so that the whole thing was in a collapsed state. He did not think they could give away any more time. Mr. Benson pointed out that if the resolution were passed the Council would be tying its hands for six months. Alderman Bevan said there was a great deal in what Mr. Thomas Jones said, and he would amend his motion to the effect that the Council would not object to the extension on condition that it was the last. This was agreed to and the motion was carried.

Toxteth Park.—Mr. John Price, A.M.I.C.E, engineer and surveyor to the Urban District Council of Toxteth Park, has issued his annual report for 1894-95. He states that during the year electric lighting mains were laid, under the supervision of the electric inspector, in Croxteth-road, Ullet-road, Greenbank-drive, and Lathbury-lane. The number of houses supplied with the electric light at the end of the year was 38, being only an increase of nine for the 12 months During the year the Liverpool Electric Supply Company gave notice of their intention to apply to the Board of Trade for a new provisional order, to amend the existing orders, in case of the incorporation of the Council district. In connection with the refuse-destructor works which have been erected, after receiving reports upon the relative cost of lighting the works by gas or electricity, it was decided to adopt the latter method, the necessary power being already provided. Mr. W. G. P. Macmuldrow, the electric inspector to the Corporation of Liverpool, was called in to advise as an expert, and, upon his report, it was decided to contract only for the supply of the engine and dynamo, the rest of the work being carried out departmentally. The contract for the engine was let to Messrs. Ransome, Sims, and Jefferies, of Ipswich, and for the dynamo to the Electric Construction Company, of Wolverhampton.

Blackburn.—At the last meeting of the Town Council the minutes of the Town Hall and Public Baths Committee stated that the town clerk had submitted the tenders received for the electric lighting of the Town Hall. The committee resolved, and it was sanctioned by the Council, that it be an instruction to the town clerk to have the tenders tabulated and printed and a copy forwarded to each member of the committee, and that the consideration of the tenders be deferred to a future meeting of the committee. In referring to the minutes of the Gas Committee, Mr. E. Hamer said that it would not be wise to refuse applications for the electric light. They had had applications for 1,500 lamps, and it would be well for all purposes if the minute of the committee was referred back. In a road like Preston New-road the inhabitants would be having the light from some other source if the Corporation refused applications. That should not go forth, and he moved that the minute be referred back. Mr. Oddie seconded, and during the course of further discussion it was thought that the present system should first be thoroughly tested before they went in for extension. Alderman W. Thompson, contending that there would be no harm in referring the minute back, said one statement made by one speaker was wrong to the extent that it would not cost as much to put up the proposed light per lamp as the installation they had now. Alderman Harrison did not think that 1,500 lamps would be applied for. The amendment was ultimately carried.

Edinburgh —The public electric lighting system of the Corporation has been extended as far east as the foot of Canongate, and as far south as Hope Park, and in the case of Canongate particularly the turning on of the new illuminant created a good deal of interest. At a quarter to nine o'clock on the night of the inauguration about 200 residents in the Canongate Ward assembled in the Canongate Institution, under the chairmanship of Councillor Waterston and heard a few remarks from that gentleman, and also from Councillor Mackenzie, convener of the Electric Lighting Committee, prior to repairing to the thoroughfare outside and witnessing the turning on of the current. Councillor Waterston in his remarks spoke of the boon the new light would be to the inhabitants, and stated that in view of the nature of the street and the character of its buildings, the Canongate would be one of the best lighted thoroughfares in the kingdom. Councillor Mackenzie, on his part, expressed his pleasure at seeing this latest extension of the new light, and mentioned that so far as it had gone the Edinburgh installation was one of the most successful that was to be seen anywhere in the kingdom. Since the light was turned on in the city on April 11 it had never been off the mains for a single second. There had never been a hitch. Votes of thanks were accorded to the ward representatives and to Councillor Mackenzie. When the company adjourned to the street they found a crowd of several hundred people gathered outside the hall to watch the light turned on.

Fulham.—At the last meeting of the Vestry the Special Committee on the electric lighting of the parish, etc., reported as follows: "Before taking any further steps in the matter of electric lighting we have instructed the clerk to request the various local authorities who have had the electric light installed in their districts to furnish this Vestry with the best information they can give upon the following points: (1) The number of shops and other places of business within the area of supply and the number of such shops and places of business taking the light; (2) the number of private houses in the area of supply and the number of such houses taking the light. This information to be supplied, if possible, in a tabular form showing the ratable value of the shops and houses supplied, thus (1) ratable value below £40; (2)

Digitized by Google

between £40 and £50; (3) between £50 and £75; (4) between £75 and £100; (5) between £100 and £150; (6) between £150 and £200; and (7) above £200. (3) As to public lighting: (*a*) length of roads lighted; (*b*) the system of gas lighting in use and its cost previous to the adoption of the electric light, including all expenses; (*c*) the amounts charged to the local authority for lighting the same roads by electricity and the number and kind of lights used." Mr. Comben moved as an amendment that the committee's report of July 17 be adopted. This was seconded by Mr Marks. The amendment was lost, four voting for and nine against. Mr. Sayer proposed another amendment that the matter be referred back for the committee to select three electrical experts and recommend the Vestry that one be appointed. This amendment was also defeated, six voting for and 18 against. The report was then adopted.

Kingston-on-Thames.—At the last meeting of the Town Council, the Town Clerk reported that the Local Government Board had sanctioned the borrowing of £7,772 on the electric lighting account for a term of 25 years instead of 15 years, to which it was originally limited. It was decided to seal a mortgage to Parr's Banking Company for the loan of this sum at 3¼ per cent. The Lighting Committee reported that the electrical engineer had been instructed to submit an estimate of the cost of wiring the sewage works for the electric light, and for supplying current, and that the town clerk had been directed to enquire whether Surbiton and Hampton Wick were prepared to be supplied with current from the Kingston electric lighting works. The Surbiton District Council replied stating that they proposed to have their own electric works. The town clerk was told to inform the Malden District Council that the Corporation would supply Coombe with the electric current on the necessary arrangements being made. The Engineer stated that the receipts for the supply of electricity and for meter rents for the half-year ending June 30 were £731. 4s. 1d. compared with £336. 10s. for the corresponding half last year. The committee had resolved: "That, subject to the approval of the Council, consumers of electric current be offered the following arrangements in regard to their payment for current—namely, that the present price of 6d. per unit be charged until the consumer has consumed sufficient current to average a daily use for two hours of the number of lamps he has had burning simultaneously, and that all additional current consumed be charged for at a reduced price of 4d. per unit—that is, one third less, it being found that a similar arrangement has worked advantageously both to the consumer and to the producer in other towns, such, for instance, as Brighton."

Blackpool.—The Corporation are prepared to receive tenders for the right of user for a period of seven years of the tramways in Lytham-road in the borough, authorised and constructed under the Blackpool Corporation Tramways Order, 1893. These tramways extend northwards from the southern boundary of the borough, and are about two miles in length. The motive power will be required to be electrical, and the systems to be used must be an approved overhead wire and trolley system from the southern boundary of the borough to the northerly side of Station-road, and for the remainder of the route the electrical conduit or centre-channel system now laid down by the Corporation in the roadway. The lessee must provide the plant required for generating the electrical energy, also all carriages for working the tramways and all appliances for the overhead wire and trolley system along the portion of route to be worked thereby, but he will allowed to use the electrical conduit or centre channel in the remainder of the route. The Corporation will reserve to themselves and any of their lessees of their other tramways in the borough, now or hereafter laid, the right of user of the portion of tramways in Lytham-road from Station-road northwards, including the electrical conduit or centre channel, and demanding and taking toll thereover, and the lessee must perform, observe, and comply with all requirements of the provisional order, and of all Acts of Parliament and by-laws from time to time in force affecting the tramways, and which ought to be performed, observed, and complied with by the lessee. The lease will be prepared by the town clerk of Blackpool, and will contain usual and proper provisions for the working of the tramways by the lessee, and will be subject to the approval of the Board of Trade. Tenders, under seal, stating the amount of the proposed annual rent, and endorsed "Lytham-road Tramways," to be delivered to the town clerk by the 17th inst.

Cardiff.—A meeting of the Cardiff Free Library Building Committee was held on Friday, presided over by Alderman David Jones. The architect (Mr. Seward) presented tenders and designs for electric light fittings for the free library. It appeared that some of the designs had not been discussed between the chief librarian (Mr. Ballinger) and the architect, and the committee could not, therefore, come to any decision on the matter. The question of the number of fittings for the tables was the chief matter for consideration. The Librarian said the matter could be disposed of in a quarter of an hour, and the Chairman then rose saying that he would vote that the committee retire for a quarter of an hour while the librarian and architect settled the matter. The committee having retired some slight modification in the designs was made, and on the reassembling of the committee the tenders were opened. On the proposition of Alderman Rees, the tender of Messrs. Thomas Brown and Co., of 64, Clement-street, Birmingham, was accepted. A meeting of the Corporation Finance Committee was held on the 1st inst. at the Town Hall to consider the estimates of the various committees, in respect of which a general district rate is to be made to cover the expenditure for the six months from September 30 next to March 31, 1896. The Lighting and Electrical Committee's estimate for street-lighting for the 12 months was: for gas, £5,400; electric light, £900; labour, £2,650; materials, etc., £400; making with other items a total of £10,029. Under the head, electric lighting also for twelve months, appeared the following items: labour, £2,305; coal, stores, etc., £1,200; carbons for arc lamps, £200; rent of depôt in town, £52; water, £100; insurance of men, boilers, and buildings, £25; printing, advertising, and stationery £50; contingencies, £200; making a total of £4,132 less £2,700, estimated revenue the balance of £1,432 added to the £10,029, representing a total of £11,461.

Dover.—At the Town Council's last meeting a report from the Lighting Committees of the Town and Pier Wards on the position of the electric lights in Snargate street was due but not forthcoming. Councillor Thorpe explained that as the notice received from the town clerk contained a paragraph in which it was stated that the experienced officials of the electric light company would fix the exact locality of each lamp, as their experience would enable them to do this to the best advantage, they did not see the use of the committee meeting. He also pointed out that the agreement with the company threw on the Corporation the onus of obtaining leave from the owners to put up the arches. He gave notice that he should move that the resolution passed in reference to the lighting of Snargate street by electricity be rescinded. If they had to find the sites, no doubt the owners would want paying, and it was altogether too much, considering the excessive charge of £30 per lamp. He asked if they were in a position to spend that money. The 21 lamps they already had cost them £650, and the 10 more £300. He wished to know why the gas company had not been asked to send in a price to compete with the electric light. At present they had 24 lamps at a cost of £5. 1s. each, and if they were to have the incandescent burners similar to Maison Dieu-road, it would only cost £3. 15s. He should propose to increase the lamps to 32, when the cost would be the same, and they would have an equal light to what the electric light would give. Alderman Peake said that it was a snatch vote by which they decided to pay the £300. He thought it could be spent for better purposes, and although he spoke as a gas director, he also spoke as a ratepayer, and his remarks would receive a good deal of support outside. A letter was also read from the electric light company asking for an appointment to meet the Lighting Committees of the wards. A long discussion took place, in which Councillors Clark, Mackenzie, and G. Mowll took part, but no conclusion was arrived at, Councillor Thorpe's motion in the meantime having stopped any further steps.

Edison and Swan United Electric Light Company, Limited.—An extraordinary general meeting of the Edison and Swan United Electric Light Company, Limited, will be held at the offices of the Company, Ediswan Buildings, 36 and 37, Queen-street, Cheapside, in the City of London, on Friday, August 16, 1895, at one o'clock in the afternoon, when the subjoined resolution, which was duly passed at the ordinary general meeting of the Company held on July 29, 1895, will be submitted for confirmation as a special resolution under the Companies Acts—viz., "Resolved that the articles of association of the Company be altered by striking out Article 87 and substituting therefor the following articles: 87. The amount from time to time declared by the Board as available for dividend, including the amount, if any, recommended by them to be withdrawn from reserve for equalisation of dividends, shall be applied as follows: (1) There shall be first set aside thereout a sum equal to a preferential cumulative dividend of 7 per cent. per annum on the aggregate amount for the time being paid or credited as paid on the A shares. (2) Out of the sum so set aside there shall be paid a preferential cumulative dividend at the rate of 5 per cent. per annum on the amounts paid or credited as paid on the A shares without distinction. (3) Subject thereto there shall be paid out of the sum so set aside a further cumulative dividend at the rate of 2 per cent. per annum on the amount paid or credited as paid on the A shares provided that until all the A shares be fully paid no A share, whether fully paid or not, shall for the purpose of this sub-section be deemed to have paid upon it more than the amount paid up or called up upon the A shares for the time being having the least amount called up or paid thereon. (4) The balance of the sum so directed to be set aside shall be carried to the reserve fund. (5) The residue of the amount declared to be available for dividend after setting aside the sum mentioned in Sub-section 1 shall be applied in payment of dividends *pari passu* on the amounts paid up or credited as paid on the A and B shares, but so that for the purposes of this sub-section the amounts to be deemed paid up on the A shares shall be ascertained, as in the case of Sub-section 3."

Derby.—A Local Government Board enquiry has been held by Colonel Wm. Ducat into the application of the Corporation to borrow £13,000 for electric lighting purposes. The Board have already sanctioned £35,000, and the additional money is required for the actual expenditure above the sum previously granted. At Wednesday's meeting of the Town Council, Alderman Leech moved the adoption of the report of the Electric Lighting Committee, which was as follows: "The Council on March 6, 1895, granted the sum of £5,000 for works, etc., as under: alteration of premises adjoining the station, £1,000; additional distributing and connecting mains, £2,000; three additional boilers, £2,000; total, £5,000. The committee have had specifications prepared and have invited tenders for building boiler seatings for the three new boilers and for building the new coal-store at the station, and the tender of Mr. George Wagg (£1,965) has, subject to the approval of the Council, been accepted. The committee have also ordered an additional flue to the three boilers which are now being constructed at a cost of £80. The cost of the three boilers is £1,479. 15s. Assuming that the £2,000 for

Digitized by Google

mains is sufficient, it will be seen that a further sum of about £524 will be required to complete these works. The Council is asked to grant the sum of £524, and to direct application to the Local Government Board for the borrowing thereof. In consequence of the still rapid increase in the demand for electricity, the committee have had under their consideration the desirability of enlarging the present station so as to cope with the supply, and it has been decided to recommend the Council to grant a sum of £3,490 to enable them to build an annexe to the present station and to provide a 250-h.p. engine and alternator with exciter, including steam-pipes and all connections and additions to the switchboard. The Council is requested to pass the resolution placed upon the agenda, granting the amount, and directing application to the Local Government Board for the borrowing thereof. The committee have taken charge of the lights in the Market Hall for the Markets Committee, and of the lamps outside the Town Hall for the Estates Committee. The Employers' Liability Company, Limited, have paid the sum of £50 in full discharge of all claims in respect of the death of Samuel Woollatt, one of the arc lamp trimmers, who was killed by falling from an electric light lamp. The amount has been paid to the deceased's administratrix. The committee beg to report that the borough accountant, acting upon their instructions, has prepared a capital and revenue account of the electric lighting undertaking." The report was adopted after discussion.

Brighton.—The borough surveyor has presented a report to the General Purposes Committee of the Town Council with regard to the proposed passenger lift at the Town Hall, pointing out that there were two kinds of lifts in use—viz, those worked by hydraulic power and others worked by electric current. The electric lifts were very generally adopted now instead of hydraulic lifts, and they frequently superseded existing hydraulic lifts. The cost of a hydraulic lift, suitable for use in the Town Hall, would be £357. The cost of an electric lift of the same capacity would be £538. The cost of working a hydraulic lift with water would be slightly less than the cost of working an electric lift with electricity, but in either case, assuming that the lift would make from 150 to 180 journeys a day, the cost would not exceed about £10 a year. The cost of maintenance would be about the same in either case. There were upwards of 2,000 lifts worked by electricity in this country at the present time, and recognising the value of electricity as a motive power, he strongly recommended the Council to adopt an electric lift for use in the Town Hall. The committee resolved that the borough surveyor be instructed to provide an electric lift for the Town Hall at an estimated cost of £538. Alderman Reeves, in moving the adoption of the proceedings of the committee at the last meeting of the Town Council, said he had been asked to give some explanation as to the decision of the committee in favour of electricity as a motive power for the lift at the Town Hall. He could, however, only say that it was a very strong committee, and that the general verdict was for electricity. He did not ask each member what was in his mind when he voted. Councillor Wilson questioned the correctness of the estimated cost of working the lift. From his experience of hydraulic lifts, and having regard to the statement by the surveyor that electricity would cost more, he suggested that £10 was a misprint for £100. Alderman Sendall said he and other members had hesitated in accepting the estimate, but they had before them in writing the statement of the surveyor; and Councillor Stafford assured the Council that the cost per journey would be only about a farthing, and that when the lift was not working the electricity could be switched off. Councillor Greenyer pointed out that a farthing a journey upon the basis of the committee's estimate would show a cost of over £50 a year. Councillor Wilson said he did not object to the proposal as to the lift; his object was merely to draw attention to what he believed to be a mistake in the estimate, and Councillors Baker, Berry, and Broadbridge having referred to the futility of debating the point when they were all agreed to have the lift, whether it cost £50 or only £10, the proceedings were agreed to.

Bangor (Wales).—At the monthly meeting of the Bangor City Council on Wednesday, the Mayor (Alderman Dr. R. Longford Jones) presiding, the Electric Lighting Committee reported that Mr. Meadows had presented his amended report and estimate as to the proposed electric lighting works, and that after considering the same the committee unanimously resolved that the Council be recommended to apply for a license, and that the committee be empowered to take whatever steps it may find necessary to carry out the scheme. On these minutes coming up for confirmation, Alderman Thomas Lewis, chairman of the committee, expressed himself unwilling to propose their confirmation. The further he looked into the matter the less inclined he felt to go on with the scheme. Dr. Grey Edwards thereupon moved the adoption of the minutes. The scheme, he said, had been most favourably reported upon, and enquiries made in other towns where the electric light was in use were equally favourable. They should not miss that opportunity of acquiring the necessary powers. Liverpool had missed its opportunity in this respect and a company had taken the matter up, with the result that Liverpool had now to pay through the nose for its remissness to the tune of something like £400,000. Councillor Robert Hughes, in seconding the motion, expressed great surprise at the defection of the chairman, who at the last meeting of the committee was quite enthusiastic in favour of the scheme. Dr. Rowland Jones felt convinced that it was inevitable that the town should be electrically lighted, and the only question was which scheme should be adopted. Alderman Thomas Lewis explained that further enquiries which he had made showed that no favourable reports had been received from such a small place as Bangor. They must also remember that another expert, Mr. Newbiggin, had said quite the opposite to Mr. Meadows as to electric lighting in small towns. Reference had been made to favourable replies to enquiries received from other towns where the electric light was in use. He would take the most roseate of these, the reply from Taunton. What did the figures show? Mr. Meadows had told the Bangor Council that in a year they would have 4,000 lights in use. But in Taunton, a place with double the population, and after four years' working, they had only 4,500 lights in use. Therefore, he (Alderman Thomas Lewis) could not see how they were going to get 4,000 lights going in Bangor in one year. He further found from the figures that the total receipts at Taunton were £2,079, and they had to pay in interest and dividend £420, and to the sinking fund £436. Such figures indicated an immense call on the rates of the town, even after four years' working. He moved, and Dr. Rowland Jones seconded, that the matter be referred back for further consideration. Dr. Grey Edwards, however, withdrew his motion, and moved the amendment, and the proposals of the committee were accordingly referred back.

Cheltenham.—A meeting of the Town Council was held on Tuesday, at which the Lighting Committee reported that since the last meeting the electric light cable had been laid from Cambray to the Belle Vue Hotel, and the borough engineer was daily expecting the delivery of the lengths for the Evesham-road; that an application had been received from Messrs. Webb Bros. for 2-b.h.p. motor at Alstone for chaff-cutting, etc., which would involve a length of 1,000ft. of supply from the Arle-road main, or if the new main is laid along Alstone Croft, of 350ft., and an increase of the length of the main of about 300ft.; that an application had been received from Mr. Henry Chapman for a supply to The Grove, Douro-road, which would involve an extension of about 250 yards; that an application had been received from Mr. W. B. Bingham for a supply to Rose Hill, which would involve an extension of the main in Evesham-road for a distance of about 800 yards, and that the cost of these extensions would be as follows: Messrs. Webb, Alstone, £35; Mr. Chapman, The Grove, £42; Mr. Bingham, Rose Hill, £130. It would be necessary, in view of the amount of energy applied for, to take into consideration the advisability of ordering an additional engine and alternator. It was resolved that the applications be acceded to, subject, as regards Messrs. Webb, to the minimum charge being £7 per annum, as regards Mr. Chapman to the minimum charge being £8 8s. per annum, and as regards Mr. Bingham's application, to the consent of the County Council being given to the laying down of the cable in the main road outside the parish. In view of the number of applications for supply of the electric light involving extension of the mains and provision of additional machinery, it was resolved to apply to the Local Government Board for sanction to borrow a further sum of £10,000. Mr. G. H. Williams, secretary to the Theatre Company, wrote with reference to the Streets Committee's promise to fix an additional lamp in Ormond-place and readjust the lamps in Regent-street, and the matter was adjourned pending the question of lighting the Promenade with electricity. A letter was read from Mr. C. H. Whitmore complaining that the wall of 48 St. George's-place had been injured during the construction of the electric light testing station. The town clerk's reply, stating that in the surveyor's opinion no damage was done by the builder, and that in any case the contractor and not the Corporation would be liable, was approved. Mr. Ticehurst, clerk to the Assessment Committee, wrote that he had advised his committee to assess the electric light works in the first instance at not less than £320 per annum, and to have as soon as possible a valuation by an expert. The town clerk's reply, informing him that as the matter then stood the Lighting Committee must appeal to the special sessions against the assessment, was approved. Alderman Norman proposed the adoption of these minutes, and this was agreed to.

Hampstead.—The Lighting Committee of the Vestry have recommended that two spare coils of each of the three sizes of armatures used on the alternators at the station be obtained at an estimated cost of £36; that a high-tension recording Thomson wattmeter, for checking the output of the station, be obtained at an estimated cost of £30; that an eight-day clock for the station be obtained at a cost of £2 5s; that a double set of indicators for the engines be obtained at a cost of £20; that covers for all the dynamos, to prevent breakdown by dust, be obtained at a cost of £9 9s.; that 2in. cast-iron pipes be laid from West End-lane to High-road, Kilburn, at a cost of £187; that the Vestry do approve of the order given by the engineer, as a matter of urgency, for two dozen house service boxes, at a cost of £91. 4s; that 500 yards of 19/17 house connecting cable be obtained at a cost of £79. 3s 4d.; that a small hand pump, to raise the water which accumulates in the coal-elevator, be obtained at a cost of £6. 10s.; and that the Vestry do approve of the order given by the engineer, as a matter of urgency, for certain small articles required in working the station, such as fire-bricks for boilers, worm and wheel for stokers, new valve for economiser, etc. The Vestry have adopted the report. The committee further reported at last week's meeting of the Vestry that they found that on June 22 11,000 8 c.p. lamps were connected to the Vestry's mains; that owing to the large extension now being made and to the applications from new customers it is calculated that at least 20,000 8-c.p. lamps will be connected to the mains by Christmas next; that the total capacity of the present plant at the station is 12,000 8-c.p. lamps; and they recommended that another plant similar to the large unit at present in the station, be ordered at once at the estimated cost of £2,325. Mr. Richardson called attention to the fact that Messrs. Siemens Bros. at first offered to supply this plant for £1,965, and suggested that the Vestry should

Digitized by Google

go into the open market and buy what they required. In reply to the chairman, Mr. Cottam said that it would be wiser to have this supply from Messrs. Siemens, because, if anything should go wrong afterwards, it would be difficult to say where the fault lay if engines of different type were running side by side. Messrs. Siemens asked for an increased price because the Vestry had not, they said, adhered to the original contract, but had made purchases elsewhere. After some discussion the recommendation was referred back to the committee for further consideration, with power to act. A letter was received from the Board of Trade, forwarding copy memorandum of Major Cardew, R E., with reference to the application of the Vestry for the consent of the Board to the placing of four 25-kilowatt transformers in certain sub-stations erected in the parish. It was stated that in the circumstances they were unable to consent to the increased power, and special attention was called to the remarks as to the absence of proper ventilation in the chambers and as to the fuse boards and leads. This was referred to the Lighting Committee.

Limerick.—A meeting of the Corporation was held on Thursday last week, at which Mr. Bourke proposed that the necessary steps should be taken to put in force the provisional order obtained from the Board of Trade as to electric lighting. He said they might be a little behind other places—50 or 100 years—occasionally, but he should like very much that in regard to this question they should not be in the same position they were in with regard to the water and gas concerns, when they had to purchase the interests of rival establishments already in existence, and at very great expense. In both these cases—the water and gas concerns—the Corporation were the losers, because their forefathers had not sufficient enterprise to be the first in the field with reference to the introduction of those things into the city. In this case of the electric lighting of the city he hoped they would not allow the same thing to occur, but that the Corporation would take steps to retain for itself what it undoubtedly had a right to, the sole right, under the provisional order obtained from the Board of Trade, of supplying electric light to the citizens. The only thing that occurred to him to say was that Prof. Kennedy in his report over-estimated to a great extent the probable and immediate wants of Limerick in respect of electricity, and also over-estimated the probable consumption of electricity in Limerick for a good many years to come. Prof. Kennedy, he noticed, made comparisons with some English and Scotch towns of similar size, but which had undoubtedly more wealth, and where electric light was more used than it would be there He thought that they need not anticipate anything like the outlay mentioned by Prof. Kennedy—£18,000. Mr. Spillane mentioned that he could afford the Council very little information in addition to what was contained in Prof. Kennedy's report. The history of the project was familiar to the members. In 1892 their hands were forced to apply for a provisional order from the Board of Trade because two different companies served notice on the Corporation they were going to apply to the Board of Trade for powers to supply electricity to the city; and whether it was they were influenced by what took place with regard to the water and gas supplies, the Council so decided and got the provisional order. The expenses in connection therewith was £430, and the fee paid to Prof. Kennedy was 100 guineas, that being the outlay on the matter so far. The question now was whether they would stop or halt, which was the same thing, because, unless the Council proceeded in a very short time indeed, the Corporation might find the Board of Trade revoking their provisional order granted two years ago and grant a license to any company applying for it, no matter from what particular part of the globe that company might come. The time of the Corporation to give effect to the provisional order expired at the end of the year 1894, and they were on sufferance since, having now reached August 1, 1895. If any company applied to the Board of Trade, and undertook to supply the electricity, they would get a license, unless the Corporation took the matter up at once. He did not believe they would require £18,000, but that they could get the money as they wanted it from the Board, the power of getting the loan following on the granting of the provisional order. The gas concern cost £54,000, and of that sum £17 000 remained due. The total cost would be cleared off in 1899. Mr. Dundon, in answer to Mr. Clune, said he believed, as matters stood, the Board of Trade would grant a license to any of three companies now proposing to supply the city with electric light. He suggested a modification of the resolution, and it was agreed to. On the motion of Mr. Bourke, seconded by Mr. Gaffney, it was decided by 21 votes to 4 to call on the Local Government Board to hold an enquiry with a view to obtaining a loan for the purpose of introducing the electric lighting into the city in pursuance of the provisional order obtained by the Town Council.

Hastings.—A meeting of the Town Council was held on Friday last. The Roads Committee reported that they had received from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, amended notice of the intention of the company (*a*) to carry a 7/20 concentric high-tension main from their works in Earl-street, up Priory-avenue to the junction of Stanley-road, crossing the railway bridge on the outside bottom edge of girder; (*b*) to construct an inspection-box on the upper side of the junction of Braybrooke-road with Priory-avenue, and another at the lower side of the junction of Stanley-road with Priory-avenue; (*c*) to carry low-tension cable from the first-mentioned inspection-box to the end of Stanley-road, and to construct a brick box at either end of Stanley-road aforesaid, to carry another low-tension cable from the said inspection-box northward, along the west side of Braybrooke-road (towards Park-road) to a brick box to be constructed at a point opposite No. 131, and to cross the road to that house; (*d*) to carry a low-tension main from the said inspection-box, across the road to 98, Braybrooke-road, and another piece of similar main from the same box, a distance of about 30 yards, southward, along the west side of Braybrooke-road (towards the railway station), such works to be carried out and constructed in manner specified in the notice, and in accordance with a plan submitted therewith. The committee recommended that such plan be approved subject to the respective works being carried out to the satisfaction of the borough engineer, and to the company giving the usual undertaking not to remove the covers of the boxes, except between the hours of 10 p.m. and 9 a.m., unless in case of actual emergency. The recommendation was passed. The Public Lighting Committee stated that they had been in communication with the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, with a view to ascertaining the terms upon which the company would supply the two electric lamps proposed to be placed on the baths at White Rock, and had received a letter from the secretary to the company stating that his directors had carefully considered the matter, and found that £40 per lamp per annum was the amount they must ask. The committee had informed the company that they could not entertain the offer, and recommended that the proposal to erect electric lamps be abandoned. Alderman Tree said that as he brought the matter forward to the notice of the Council, he would like to propose, seeing the committee recommended that the proposal be abandoned, that the recommendation be adopted. He would have that entered on the minutes, but would further recommend that the question of lighting by other means be referred back to the committee, with instructions to make a further report. The price, £40 per year, was a most extravagant sum, and the electric light company had made a grand mistake in putting the price so high. He would never think of voting for such expense, and he thought some other means of lighting might be found for the south side of the baths, as it was urgently necessary. Councillor Chapman, as a member of the Lighting Committee, said the committee were of opinion that a light should be provided for that side of the baths, but none of them would ever think of paying the enormous price of £40 a lamp. He would second the proposal that the question of lighting be referred back to the committee. Councillor Burrell pointed out that the electric light company only charged £25 for the lamps now in use, and he could not see why an extra £15 each should be asked for two more of exactly similar kind. Councillor Tuppenny considered the reason the electric light company charged extra for these two was because they had lost money by the others, and it was their intention to recoup themselves out of those additional lights as far as possible There were differences of opinion as to the lamp which would be suitable for the purpose. The Mayor added his testimony to the fact that additional lighting was necessary at this point. The adoption of the report was put to the vote and carried.

West Riding Telephones.—The question of promoting a private service of telephones for the purposes of the West Riding constabulary has recently engaged the attention of the West Riding Standing Joint Sub-Committee. The committee have had two schemes before them. The larger scheme provides for the following divisional headquarters and sectional stations (county property) being connected with headquarters at Wakefield, the sectional stations being given in parenthesis: Wakefield (Normanton), Barnsley (Penistone), Rotherham (Rawmarsh), Doncaster (Mexborough), Pontefract (Castleford), Goole. Sheffield (Hillsborough), Tadcaster, Knaresborough (Ripon and Harrogate), Otley (Ilkley), Leeds, Keighley (Bingley), Bradford (Shipley, Pudsey, and Cleckheaton), Halifax (Brighouse and Elland), Saddleworth, Huddersfield (Holmfirth and Honley), Dewsbury (Batley, Heckmondwike, Morley, and Mirfield), and Todmorden (Hebden Bridge). The smaller scheme provides for the connection of the divisional headquarters named above only. Mr. W. E. L. Gaine, manager of the National Telephone Company, has written a letter to the sub-committee, in which he says: "Full detailed estimates of the two schemes submitted by Captain Russell have been got out and placed before me. The larger scheme will involve a capital outlay in material and labour alone, without any addition for engineering and administration, of £8,140, and the smaller scheme will, in like manner, involve a capital outlay of £6,080. The very lowest annual charge which the company can afford to make, if it is not to incur serious loss, is £1 436 (say, £1 400) on a 15 years' contract in respect of the larger scheme, and £1,059 (say, £1 000) on a like contract in respect of the smaller scheme. The larger scheme involves the erection and up-keep of 664 miles of wire, and the smaller of 492 miles. The figures are less than those given you previously, and are arrived at by extending the term of the contract from 10 to 15 years, and giving the county the full benefit of the lowest rate at which the company can borrow its money. They will leave the company without a shilling profit and with a possible loss. It must be borne in mind that the recent agreement which has been made between the Government and the company for the acquisition by the Government of the company's trunk lines has materially altered the situation, as out of 3,800 poles on the main roads, only about 1,700 are now the property of the company, the remainder having been acquired by the Government, and these latter will be taken over by the Government within the next few months and so soon as the arrangements can be carried out. Having regard to the fact that the company is affording to the county a large amount of exchange service, free of charge, in addition to paying the present way-leave charges in respect of the 1,700 poles remaining the property of the company, which makes the way-leave in respect of those poles a high one, it is only

Digitized by Google

reasonable that the company should, in respect of the police contract, have a profit upon the transaction after the poles which have been acquired by the Government have been handed over; but, in view of the very strong representations you have made to me, and the desire of the company to maintain amicable relations with the county, and in full reliance that the county will render in the future every assistance it can to the company in the development and extension of the telephone service, I am prepared to advise the company to waive any question of profit, and to accept the contract at the figures I have named, for the full term. In view of the fact that the Government will, in the course of the next few months, take over the poles which they have acquired, it is essential that the wires for the police contract should be erected before the actual transfer, otherwise the company will be unable to carry out the contract without the consent of the Government, which, of course, may be refused. The company has a free hand until the transfer, but afterwards has no right to erect wires on the Government poles, though it has the right of having any existing wires maintained." The Standing Joint Sub-Committee recommend the adoption of the larger scheme, subject to satisfactory terms being arranged. It is suggested that the terms should include a condition that the wires and other erections, the cost of which is defrayed out of the sum of £8.140 referred to in Mr. Gaine's letter, should be the property of the County Council at the expiration of the lease and the sub-committee are of opinion that the rate of interest should be calculated at the rate of not more than 4 per cent. per annum.

PROVISIONAL PATENTS, 1895.

JULY 29.

14355. **A non-rotating terminal for wire or cable connections to electrical instruments and the like.** Charles Berry, 55, Fitzwilliam street, Huddersfield.

14360 **Improvements in bayonet-joint holders for incandescent electric lamps.** John Howard Pentland, Lis-na-Crun, Cowper-road, Rathmines co Dublin.

14393. **Improvements in voltaic batteries.** Desmond Gerald Fitz-Gerald, 53, Chancery-lane, London.

14403 **Improvements in or connected with electrical gas-igniting devices.** Jean Jahnsson, 45, Southampton-buildings, Chancery-lane, London.

JULY 30.

14446. **A combined astatic and dead-beat galvanometer especially for use on board ship.** Thomas Clark, 31, Southampton-buildings, Chancery-lane, London.

14473. **Improvements in and relating to electric clocks.** William Soule Scales, 45, Southampton buildings, Chancery-lane, London.

14476. **Improvements in transmitting and receiving attachments for telephones.** Horea Waite Libbey, 45, Southampton-buildings Chancery-lane, London.

14481. **An improvement in imitation candles for electric lights** Thomas George Poole and William Lowry, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14485. **Improvements in alternating-current arc lamps.** James Devonshire, 70, Chancery-lane, London. (Charles E Harthan United States.) (Complete specification.)

14486. **Improvements in four-motor reversing switches.** James Devonshire, 70, Chancery-lane, London. (Frank E. Case, United States.) (Complete specification.)

14492. **An improved arc regulator for electric lamps** Sinforoso Prieto, 18, Buckingham street, Strand, London. (Complete specification.)

14493. **Improvements in electromotors and dynamos.** Thomas Drake Hollick and Frederick William Hollick, 65, Chancery-lane, London.

AUGUST 1.

14577. **Improvements in multiple-circuit dynamo-electric machinery.** Charles Brooke Crawshaw and Rankin Kennedy, Hubert-street, Leeds road, Bradford.

14589. **Improvements in starting switches for electromotors and in apparatus therefor.** Charles Brooke Crawshaw and Rankin Kennedy, Hubert-street, Leeds-road, Bradford.

14615. **New or improved device applicable for use in connection with telephones.** Emma Delaney, 6, Lord-street, Liverpool.

14627. **Improvements in electric fire-alarms** Alfred Charles Brown and George Richard Neilson, 129, Algernon-road, Lewisham, London.

14638. **Improvements in electric brakes.** Joseph Crawhall Chapman, 70, Chancery-lane, London. (William B Potter, United States.) (Complete specification.)

14639. **Improvements in safety appliances for electric cars** Joseph Crawhall Chapman, 70, Chancery-lane, London. (William B. Potter, United States.) (Complete specification.)

AUGUST 2.

14676. **Improvements in shade holders for electrical and other lamps.** Hugo Hirst and William Everett Gibson, 73, St. Stephen's-road, Upton Park, London,

14709. **Improvements in electric arc lamps.** William James Davy, 40, Chancery-lane, London.

AUGUST 3.

14739. **Improvements in holders for incandescent electric lamps.** Jan Meines Huisman and Henry Charles Gover, 62, St Vincent-street, Glasgow.

14792. **Improvements in electric arc lamps.** The Rogers Arc Lamp Company, Limited, and James William Rogers, 24, Southampton-buildings, Chancery-lane, London. Complete specification.)

SPECIFICATIONS PUBLISHED.

1892.

7029 **Electric cables.** Hardingham. (Felten and Guilleaume.) (Second edition.)

1894.

11211. **Railway electrical signalling apparatus.** Grimes.
11320. **Telegraphic transmission.** Lake. (Pupin.)
13636 **Transmitting telegraphic messages, etc.** Whawell.
16542. **Search-light projectors.** Furneaux and Walker.
16918 **Electric conductors.** Fox.
17357. **Arc lamps.** Allin and Wood.
17369 **Secondary voltaic batteries.** Epstein.
17566. **Electrodes.** Schäfer and Heinemann.
25215 **Electrically-propelled vehicles.** Baker and others.

1895.

7548. **Controlling electric currents** Siemens Bros. and Co. Limited. (Siemens and Halske.)
9704. **Electric rail or tram switches.** Porter.
10836. **Storage batteries.** Payen.
10929. **Electrolysing chloride solutions.** Hermite and others.
11283. **Electric fuse heads.** Pettinger.
11375. **Covering for electric wires.** Randall and Shallcross.
11399 **Arc lamp.** Parmly.
11478. **Electrolytical separation of precious metals.** Johnson. (Pelatan and another.)
11540. **Electric primer.** Morris Tube Ammunition and Safety Range Company, Limited, and Wyatt.

NOTES.

Mining Institute of Scotland.—A meeting of this institute was held in the hall of the Royal Scottish Society of Arts, George-street, Edinburgh, on Saturday. Mr. Mitchell, president, occupied the chair and read a paper on "Electric Coal-Cutting at Glencleland Colliery."

The Pacific Cable Project.—A Reuter's telegram from Victoria (British Columbia) reports that it is stated here that Mr. F. W. Mackay, the Canadian Pacific Railway, and a number of San Francisco capitalists are co-operating with a view to securing the contract for laying the projected Pacific cable.

The British Association.—Notwithstanding the pressure of his official duties, Lord Salisbury will visit Ipswich on the occasion of the meeting of the British Association, and will, in his capacity as retiring president, preside at the inaugural meeting at the Public Hall on Wednesday, September 11.

The Invention of the Electric Telegraph.—The Queen has accepted a copy of "Extracts from the Private Letters of the late Sir W. T. Cook, relating to the Invention and Development of the Electric Telegraph," which has recently been published by permission of the Institution of Electrical Engineers.

German Electric Lighthouses.—A Bremerhaven correspondent says that the lighthouse at Wangeroog is to be fitted with the electric light, and that the light of the pharos on the Rothensand at the mouth of the Weser is to be converted into an electrical one, the current for which will be conveyed by a submarine cable.

The First Use of Platinum.—It is recorded that the first Ural miners were much disgusted with platinum, and did not know what to do with the hard, dirty-looking metal. They thought that they had solved the problem of successful utilisation when they made bullets of it for their sporting muskets. The annual platinum consumption of a few years ago of four tons has, of course, increased very considerably with the development of electric lighting.

Electric Light in the Suez Canal.—Consul Gould, of Port Said, reports to the Foreign Office that the percentage of ships using the electric light to pass through the canal have been as follows: 1890, 83 per cent.; 1891, 88 per cent.; 1892, 90 per cent.; 1893, 92 per cent.; and 1894, 94 per cent. The average time in passing through the canal was in 1894: with the electric light, 19 hours 18 minutes; without the electric light, 31 hours 17 minutes.

The Telautograph.—The *Times-Herald*, of Chicago, has been the first newspaper to use the telautograph in furnishing Press despatches. That paper recently published photographic facsimiles of a number of messages in the identical handwriting of the author sent to it the previous night from prominent men who were in attendance at the League Convention in Cleveland. The instrument worked successfully over a circuit 430 miles long. The longest trial heretofore given the telautograph was between Paris and London.

The Proposed Jungfrau Railway.—The trigonometrical and photogrammetrical surveys for the construction of the proposed railway up the Jungfrau are to be completed as far as the Eiger station before next winter, and the construction of the section between Scheidegg and the Eiger glacier is to be commenced next spring. Tenders will be invited for the laying of the permanent way and for the construction of the stations and other surface works, as well as for the supply of the necessary rolling-stock and electrical appliances.

The Electricity!—Albert Greenshields, a tailor's cutter, was charged on Monday at Marlborough-street Police Court with being drunk and disorderly. The police found the accused drunk in Oxford-street on Saturday night. Instead of going away he laid down in the road. The prisoner: I fell down; I was tipsy at the time. Mr. Hannay: You must have been very far gone to fall down in the road. The prisoner: It was the electricity in the weather. I took a little drop of whisky to stop a feeling of sickness. Result, 10s. or seven days.

Electrical Communication with Lighthouses.—The members of the Royal Commission on Electrical Communication to Lighthouses and Lightships started on a tour of inspection to Denmark and the Baltic on Tuesday, the 13th instant. All the principal Danish lightships and lighthouses, both in the Baltic and North Seas, will be visited. The Post Office authorities have placed their cable ship "The Monarch" at the disposal of the Commission for this tour. The Commission expect to return to England about Friday, the 23rd instant

Electric Dispersion.—Herr P. Drude, in *Wiedemann's Annalen*, describes a method of investigating the relation between the dielectric constant of a substance and the period of the electric waves traversing it, or what may be described as the electric dispersion of the substance. If the dielectric constant decreases as the period increases, there will be normal, if it increases, anomalous dispersion. For alcohol dispersion was found to be normal, and of the same order of magnitude as its optical dispersion. Water showed abnormal dispersion with the large wave-lengths used, whereas ebonite showed no perceptible dispersion.

Electricity in Russia.—Our Russian contemporary, *Elektritchestvo*, announces that a special electrical department is about to be added to the Railway Ministry. The same journal gives a somewhat belated account of the Marien Palace electrical installation in St. Petersburg, which was inaugurated in 1893. There are 1,500 lamps. The plant was German. It is, moreover, announced that the municipal authorities of Kiev have concluded a contract with the Allgemeine Elektrizitäts-Gesellschaft for the establishment of electric light in the ancient city at a cost of one million roubles (£150,000), part of which sum the German company will take in corporation stock.

New Electrical Journals.—The latest electrical periodical to make its bow to a wondering world is entitled *Electrochimie*, and it is edited by M. Adolphe Minet, formerly manager of the aluminium works at Saint-Michel-de-Maurienne. Its programme is to comprise natural forces, electrometallurgy, industrial chemistry, applications of electricity, mechanical construction, and aluminium and its alloys. Of a slightly different character is the *Electrical Worker*, the organ of the National Brotherhood of Electrical Workers of America, which is published in St. Louis, and which is described as "devoting considersiderable space to practical matters, in addition to society gossip."

A New Tramcar Motor.—According to the *Glasgow Herald*, Mr. G. Johnston, a Glasgow engineer, has invented a new motor, which he has been running on an experimental car on the Glasgow tramways. Our contemporary lucidly explains the motor as follows: "So far as we can ascertain, the power in use is a combination of steam and electricity; but neither smoke nor steam is visible, and the car glides noiselessly along the street. The motor is contained in a box about 3ft. in height and 2ft. in diameter, and is placed on the front platform of the car immediately behind the driver." Persons managing to get an idea of what the motor is from this description deserve to be awarded a gold medal.

Digitized by Google

One Hundred and Fifty Miles an Hour by Electricity.—A *Standard* New York telegram says: "The Baldwin Locomotive Works and the Westinghouse Electric Company are such substantial concerns that the working alliance between them, which has been announced, possesses considerable industrial importance, apart from certain plans which, if realised, would revolutionise transport service. Practical men believe that the Tesla electric motor will enable any speed to be obtained that the cars and the track can endure. The promoters of this scheme contemplate perfectly level straight tracks, crossing mountains by lifts and valleys by trestles, using cars much lighter than the present ones, and each by means of its own motor travelling at a rate of 150 miles per hour."

Electrical Resonance.—According to the *Annalen der Physik und Chemie*, Mr. V. Bjerknes has collected in a long and exhaustive paper the results of his experimental and mathematical study of this subject, and he shows that for quantitative measurements of electric waves great regard must be paid to the following five conditions: (1) the time of vibration of the oscillator; (2) the time of vibration of the resonator; (3) the logarithmic decrement of the oscillator; (4) the logarithmic decrement of the resonator; (5) the constant which measures the intensity of the vibrations. He shows that resonance phenomena are in general only suitable for quantitative measures when the mean value of the logarithmic decrement of the two conductors is smaller than 1. He indicates that quantitative measures with a spark micrometer are subject to error, and that the electrometer method used by him is more suitable for the determination of the above five conditions.

Last Year's British Patents.—The twelfth report of the Comptroller-General of Patents states that, though the number of applications for patents in the year 1894 continued upon an ascending scale (being 270 more than in the previous year), this increase was considerably less than that of the normal average of the preceding seven years. The number of applications for patents has increased from 17,176 in the year 1886 to 25,386 in 1894; being at the rate of 48 per cent. It is interesting to notice a large increase in the number of applications for patents from Ireland last year as well as in 1893; while among the colonies, the largest proportionate advance is shown by Queensland. As respects similar applications from foreign States, Belgium, Germany, and Sweden had the largest increase; the number of applications from France having remained curiously stationary during the past 10 years—being 788 in 1884, and only 799 last year. The applications from the United States, which reached the number of 2,597 in 1890, have fallen off since that date, and amounted to only 2,017 in 1894.

Prof. W. R. Smith on Electric Lighting.—In the course of a speech which he delivered at the recent congress at Hull of the British Institute of Public Health, Prof. W. R. Smith, medical officer of the London School Board, and president of the institute, said that he would like to say a word in connection with a department of public health which he saw had been carried out in Hull with very important results, and from a ratepayer's point of view with the most important result of a balance to the good—he meant the electric lighting. He thought that the question of electric lighting, which they all recognised as the proper lighting for the future, and the development of which no one in that room could properly realise, was a most important one for everybody entrusted with the public health and the social advancement of their respective districts. He sincerely congratulated the Electric Lighting Committee and its able chairman, Councillor Holder, and the Corporation of Hull, upon the very successful results that had attended the experiments of the introduction of that modern development of lighting.

Economic Power Production.—A daily paper states that the supremacy of the steam-engine is threatened not only by electricity but also by gas-engines as a cheap source of motive power so essential for industrial development. Gas-engines have been brought by engineering skill to a high state of efficiency, but a great drawback, when compared with the steam-engine, has been that the gas-engine could not use ordinary steam coal and inferior fuels. It is now claimed, however, that this obstacle to the more extended use of gas-engines has been removed, and that by the invention of Mr. Thwaite, C.E., the gas-engine can compete with, and in economy of fuel surpass, the steam-engine on its own ground and with its own fuel or bituminous steam coal. Such a gas-engine is shown at work at Stoke Newington driving an electric equipment, and it is stated that peat, refuse slack coal, and ordinary steam coal have been successfully used, and this without the use of any steam boiler, thus removing a dangerous auxiliary to steam-engines, and with it the smoke nuisance and the difficulties of hard and impure water.

The Argentine Cable Question.—A meeting of the Balloon Society was held on Tuesday night, when a paper was read by Señor Juan Sauchez-Villeyas on "Gleanings from the History of Brazil and Trinidad." The author, with regard to Trinidad, stated that it was advisable for England to retain the island, to facilitate the laying down of a cable from Europe to Argentina and other South American States independent of Brazil. Mr. E. S. Roberts moved, "That, having regard to the unique and influential position of Great Britain in promoting the progress of humanity throughout the world, and the high character of the statesmanship by which her world-wide affairs were directed, it is desirable, in the interests of the nations at large, that she should retain possession of the island of Trinidad, as well as other convenient stations, which are necessary and contributory to the fulfilment of her high mission, and when it is considered that Great Britain owns seven-eighths of the submarine cables of the world, and that she has invested capital therein to the amount of £3,000,000, the commanding importance of the matter as a practical necessity cannot be exaggerated." The motion was adopted.

Horseless Carriage Contest.—A horseless carriage race between Chicago and Milwaukee, promoted by the *Times-Herald* of Chicago, will be decided on Saturday, November 2, the object being to encourage and stimulate the invention, development, perfection, and general adoption of motor carriages. The amount offered in prizes is 5,000dol., apportioned as follows: First prize.—2,000dol. and a gold medal, open to competition to the world. Second prize.—1,500dol., with a stipulation that, in the event of the first prize being awarded to a vehicle of foreign invention or manufacture, this prize shall go to the most successfully American competitor. Third prize.—1,000dol. Four prize.—500dol. The third and fourth prizes are open to all competitors, foreign and American. The rules laid down stipulate, among other things, that no vehicle shall be admitted to competition which depends in any way upon muscular exertion, except for purposes of guidance. Competing vehicles which derive their power from petroleum, gasoline, electricity, or steam, and which are provided with receptacles for storing or holding the same, will be permitted to replenish the same at Waukegan, Ill., and at Kenosha, Wis., but at no other points.

Association of Municipal and County Engineers. A meeting of the association will be held at Londonderry on the 23rd and 24th inst. The programme is as follows;

Digitized by Google

on Friday, 23rd, the members will meet in the Town Hall, Londonderry; 11.30, district business; 12, reception by the Mayor. Papers will be read on the "Electric Lighting of Londonderry," by Mr. J. Christie, city electrical engineer, and on "Municipal Electricity," by Mr. James Perry, M.I.C.E., county surveyor, Galway. After luncheon visits will be paid to the electric light station, filter beds, city walls, etc. On the 24th the members will meet at the Town Hall, Portrush, at 9.30, when papers will be read on "Fire Brigade Work," by Mr. J. Munce, A.M.I.C.E., chief assistant surveyor, Belfast Corporation, and on "Light Railways and Tramways," by Mr. R. H. Dorman, M.I.C.E., county surveyor, Armagh. The members will then leave Portrush by special electric cars, stopping at Bushmills, and visit the electric power generating station, arriving at Causeway at 1.15. Special cars will leave the Causeway at 5.45, stopping at Dunluce Castle. Mr. W. A. Traill, C.E., managing director and engineer of the electric tramway, will join the party and describe the working of the line.

The Smell of Lightning.—In connection with the thunderstorm of last Saturday evening, Sir H. W. Tyler has written to the *Times* as follows: "One of my daughters, as we were watching the storm, opened a glass door leading southward into the garden (at Pymmes-park, Edmonton), and at that instant we all appeared to be enveloped in a brilliant atmosphere of blue light, with simultaneous thunder. When the lightning disappeared and the thunder ceased we all exclaimed, 'What a smell of ozone.' This was unmistakable. We were all perfectly familiar with it, as being what we had so often experienced in the use of the Wimshurst electric influence machine and other ozone-producing agencies. It would be most interesting to know whether others have noticed similar lightning phenomena." In response to this, Mr. G. J. Symons, F.R.S., writes: "I have never personally been near enough to a flash of lightning to smell it, but Sir Henry Tyler is perfectly correct in his identification of it with ozone. The ordinary Briton does not know the smell of ozone, and therefore when a flash of lightning comes unpleasantly near he always describes it as 'brimstone' or 'sulphur.' I have scores of records of that kind, but the actual identification by Sir Henry Tyler is, I think, new. Experts know perfectly well that the odour described as 'sulphurous' was that of ozone, but I do not remember hearing of any one who actually smelt and identified it."

Institution of Junior Engineers.—The annual summer meeting of this Institution, whose headquarters are in London, takes place from 17th to 24th inst., the rendezvous being Belgium. The towns to be visited include Antwerp, where the municipal docks, M. Kryn's diamond-cutting works, and other places of interest will be opened to the member's inspection. At Ghent MM. Carel's Engine Works, M. de Hamptinne's Cotton Spinning Works, and M. Van Houtte's Nursery Gardens will be seen; at Brussels, the electric lighting station; whilst at Liége the works of the Société Cockerill, the Vieille Montagne Zinc Works, the St. Leonard Locomotive Works, the Val St. Lambert Glass Works, the Small Arms Factory, and the electric tramway installation, will be visited. In honour of the institution a banquet is to be given by the Liége section of the Society of Engineers from the university, and the members will also be the guests of the Société Cockerill. An excursion to Verviers, where the Chamber of Commerce will entertain the visitors, is arranged for the purpose of seeing works in connection with the woollen cloth industry. Here M. M. Peltzer's Works and those of M. Duesberg-Delrez, La Vesdre, and M. Hauzeur Gerard Fils, will be opened. The celebrated Gileppe reservoir, from which Verviers receives its domestic and manufacturing supply, is also included in the programme. A large number of members have notified their intention of being present at the meeting, which promises to be one of the most successful the institution has held.

Magnetic Rotation of Solutions of Hydrogen Chloride.—Mr. Otto Schönrock, in *Zeit. Physikal. Chem.*, states that the magnetic rotation of hydrogen chloride in aqueous solution, according to the observations of Perkin, is double that of its solution in isoamylic ether, and the cause has been ascribed to the electrolytic dissociation in the former solvent. The author had previously found an equal rotation in the two solvents and has therefore carefully repeated and extended his researches. Solutions of the gas in water, isoamylic ether, isoamylic alcohol, ethylic alcohol, and in mixtures of these compounds were examined. The rotations of the solvents were first obtained and then those of the solution, 25 liquids being so treated. The rotation is taken from the mean of four or five separate results, and is given in thousandths of a minute. This is an unnecessary refinement, however, as the separate results under similar conditions differ in many cases by nearly a minute. The results may be summarised by a table; values due to Perkin being added and marked*; the first column for each solvent giving concentration, the second the molecular rotation.

Water.		Amylic ether.		Amylic alcohol.		Ethylic alcohol.	
11·45	4·774	0·76	4·036	1·58	5·413	6·59	4·491
25·06	4·404	2·34	2·838	6·89	4·028	9·78	4·201
*15·63	4·419	3·45	3·322	9·49	3·809	14·64	4·232
*25·60	4·405	8·96	2·101	*25·45	3·285	*40·04	3·365

The rotation decreases with increasing concentration, not only in aqueous solutions but in those of other solvents, hence the author considers that dissociation has no effect on the magnetic rotation of solutions.

Therapeutics of High-Frequency Currents.—The paper read by Dr. Apostoli on this subject at the meeting of the British Medical Association is an important one, the *Lancet* says, and represents the direct practical application of the physiological facts brought about by D'Arsonval's experiments with animals. The current of high frequency and high potential is caused to traverse a large helix inside which the patient is placed, and the effect is to set up induction currents of a similar kind inside the patient's body. These travel in closed circuits through the tissues and produce nutritive changes, which can be recognised by their effect in increasing the elimination of carbon dioxide and of urea. The actual figures are promised at an early date. The results are good in diseases characterised by failure or impairment of nutrition, and accordingly Dr. Apostoli reports successes in anæmia and debility, gout, rhematism, neurasthenia, and hysteria. In diabetes, also, there have been some favourable cases. The principle of the localised application of electricity for the relief of disease, so ably insisted upon by Duchenne, has delayed the recognition of the important general effects to be obtained from electrical treatment. At present there is a distinct movement in favour of general electrification as a therapeutic means, and the results appear to be almost identical in character, whether the method employed be by the alternate-current electric bath, advocated by Gautier and Laret, or the high-potential induction method of D'Arsonval and Apostoli, or the electrostatic methods favoured by Vigouroux and Morton, of New York, who use the Wimshurst or some similar machine as the source of the electricity applied.

Carriage of Mails.—A Chicago paper writes as follows: "Should the City Council grant Richard E. Sherman permission and authority to construct and operate

Digitized by Google

underground electrical mail tubes, Chicago will have the finest mail distributing system in the world. Think of mails coursing through subterranean passageways at the rate of a mile a minute. Yet this is what Postmaster Hesing, Superintendent John A. Montgomery, and electrician Richard E. Sherman declare to be a demonstrated reality. Last fall the Superintendent of Mails made a trip to Philadelphia to investigate the pneumatic tube mail service in that City. Upon his return he said to electrician Sherman: 'Sherman, why can't you invent an underground apparatus which will carry all our mails? May be you don't know it, but we handle from 275 to 300 tons of mails a day. Why not get up an underground electrical-car system by which all this stuff can be transmitted from the sub-stations to the central office and thence to the depôts?' That was enough. Sherman caught the idea, returned to his laboratory, and soon perfected the system. The details were forwarded to Washington, and a patent secured June 27. Alderman Coughlin introduced an ordinance on Monday night in the City Council granting to Sherman authority to operate electrical tubes and electrical conduits for the purpose of transmitting mail packages and all other suitable commodities. The company is to pay into the city treasury 30 per cent. per annum of the gross receipts." It is difficult to find anything remarkable in this scheme. "Think of mails coursing through subterranean passageways at the rate of a mile a minute," says the Chicago paper. We have thought of it, and fail to see anything wonderful in the speed at all.

Crystal Palace School of Engineering.—The certificates awarded for the summer term at the Crystal Palace School of Practical Engineering were distributed on Friday last by Sir Robert Rawlinson, past-president of the Institution of Civil Engineers. The ceremony, which was largely attended, took place in the examination hall, situated at the base of the North Tower, where the work of the school is carried on. The reports of the examiners were read by Mr. R. G. Hodson, superintendent of the Crystal Palace School of Art, Science, and Literature. Mr. D. Allport, jun., A.M.I.C.E., who had examined the work done by the students in the mechanical section, drawing, pattern-making, and fitting, expressed himself as much pleased with the variety and thoroughness of the training. Similar satisfactory reports were made by Mr. C. S. Meik, M.I.C.E., and Mr. G. W. Aldridge, A.M.I.C.E., concerning the work in the civil engineering and electrical sections of the school, but at the same time Mr. Aldridge remarked that it was a matter for regret that so few students took advantage of the electrical department. Before distributing the awards, Sir Robert Rawlinson delivered an address to the students. After speaking very highly of the valuable training given at the school, he referred to theories as to the formation of the earth. He himself had come to the conclusion that the earth was not solid, but that it was a shell having a crust of a given thickness—in fact, a soap bubble would represent a miniature world. The earth contracted and expanded, and had no permanent stability. The certificates were afterwards distributed, among the most successful students being Messrs. W. T. Harbord, T. W. Simpson, M. A. Harenty, F. G. Brooker, E. Byron, L. N. Heberden, H. E. Kent, R. T. Burrows, L. de Ridder, J. G. McG. Pearce, and W. Riddell.

The Malignani Exhaustion Process.—Signor Arturo Malignani, the well-known electrician of Udine, has (*L'Elettricità* of August 11 says) devised a new method of producing the vacuum in incandescent lamp globes, a method which obtained a gold medal at the recent Scientific and Industrial Congress at Venice, and which has been patented in all countries. Signor Malignani commences by introducing into the evacuation tube a small portion of a special chemical composition. The lamp is fixed to the pump, and after about 20 seconds current is passed through the filament. At the expiry of 10 or 15 seconds of illumination the tube is closed, cutting off communication with the pump. When this is done the lamp is relighted, and the glass tube is heated with a gas jet at the point where the special material is situated which was inserted. This heating produces vapours which with the co-operation of the electricity have the effect of causing the vapours emanating from the filament to be precipitated into the solid state, producing a perfect vacuum in the globe. The whole operation lasts about a minute. Forty-five or more lamps can, it is affirmed, be exhausted in an hour. The great advantage claimed for the process is the avoidance of mercury. The pump is in three parts, the third portion communicating with the lamp. The filaments of the Malignani lamps are prepared as follows: about 30 sheets of white paper are placed one above the other, each of them being washed with acidified water. The pack of paper is heated to 70-80deg., which transforms it into a transparent gelatinous mass. When the paste is cooled it is subjected to great pressure and forced out of a pipe, whence it falls into a mixture of water and nitric acid; then it is washed, dried, and carbonised. Signor Malignani's establishment has, it seems, been visited by various electrical engineers of note, including Mr. Swan and Mr. Stearn; and various lamp-making firms are, it is stated, negotiating with the inventor for the right to utilise his device.

Ananias At It Again.—The following gem is from an American lay paper, but it is quoted without comment in the *Scientific American*, though one wonders "*que diable allait il faire dans cette galère.*" It serves to show that the American Press has not lost its talent for telling lies. "A lamp that will burn for 600 hours is the invention of George L. Roberts, an electrician, who sold to a tobacco company, for 80,000dol., the advertising rights of some of his electrical devices. The lamp of which Mr. Roberts is the inventor is charged with sand, into which two wires are run, which connect with one of the regulation bulbs used on all electric chandeliers. The battery is therefore the sand, but the method of charging it remains a secret with Mr. Roberts. Mr. Edison, after seeing Mr. Roberts's lamp, remarked that he thought he knew all there was to know about electricity, but Mr. Roberts had made a discovery which puzzled him greatly. Mr. Roberts presented Mr. Edison with some of this remarkable sand, but with no fear of having his secret discovered, for analysis happens in this case to kill all traces of the secret discovery. The cost of recharging each lamp is 17 cents. A friend of mine who has a contract with Mr. Roberts, having bought from him the rights of one of his inventions, tells me he would not have believed the tale of the lamp had he not seen Mr. Roberts throw a handful of sand into an ordinary tumbler, inserting two wires into the sand, and connecting the wires with an ordinary electric burner, which burned brilliantly. Mr. Roberts made his discovery in Minneapolis, in a purely accidental way. He was experimenting with acids in his laboratory and on the table was some sand, over which two wires had fallen and crossed themselves. By an accident a bottle containing a certain acid was overturned and some of the acid ran into the sand at the point where the wires crossed. The result was a series of electric sparks. At present Mr. Roberts is quite a sick man, and is in Michigan for his health. Another of his inventions is to make 72 changes of colour

Digitized by Google

in the hair, dress, tights, shoes, and so forth, of a dancer while she is in motion. The mechanism works by clockwork, and the light gleams through the fabrics from a direct current. Mr. Roberts married a daughter of Pillsbury, the great Minneapolis miller."

Experiment on Thermo-Electric Currents.—The classical experiment by means of which are rendered evident the currents that traverse a circuit formed of two metals when the solderings are at various temperatures becomes, says *La Nature*, more striking when, instead of mounting a magnetised needle upon a pivot placed in a fixed circuit, the circuit is, on the contrary, rendered movable, the magnetic field being in an invariable position. The idea of this reversal of the experiment is far from being new, since it is upon this principle that is based the radiometer devised by Dr. D'Arsonval, and greatly improved in its construction by Mr. C. V. Boys. This radiometer is a very delicate instrument of measurement which requires exceeding care and great manual skill for its construction; but the apparatus that we are going to describe operates perfectly as a demonstration instrument, without the necessity of much attention being bestowed upon it. It consists of a simple wheel placed in equilibrium upon a needle, and which the thermo-electric currents set in motion under the action of a magnetic field. This wheel is constructed with the greatest ease by bending into a circle a fine wire of an alloy of nickel and copper, found in the market under the name of white bronze or superior German silver. This alloy, when soldered to copper, has the property of giving considerable thermo-electric E.M.F., much less, doubtless, than that of bismuth or antimony, but it has the advantage of possessing a high point of fusion in addition to that of being able to be drawn out into fine wire—a condition essential for the good operating of the apparatus, the solderings of which become heated or cooled instantaneously. The rim of the wheel having been closed by solder, there is fixed upon it a certain number of diameters of very fine copper wire insulated from each other, and which are soldered after their extremity has been wound around the German-silver wire. One of these diameters receives in its centre a small disc of metal in which a slight depression has been formed. The wheel having been placed upon a needle, through the intermedium of this depression, is regulated by means of little banners suspended from some of the radii, and which, while lowering the centre of gravity of the wheel, permit of displacing it at will and rendering it horizontal. Let us suppose, now, that we heat one of the solderings by means of a candle. A difference of potential will establish itself between the opposite solderings, and an electric current, traversing the diameter that ends at the soldering, will return, in bifurcating itself, through the rim. If we place a horseshoe magnet in such a manner that it shall embrace a portion of the diameter, in the half opposite the hot soldering, the magnetic field will act upon the radius at right angles with its direction. Since, however, the action upon the rim is exerted in the direction of the radius, it would be null even were the bifurcation unequal, and the wheel will begin to revolve under the action of the couple produced. The revolution, which is slow when somewhat coarse wire is used, becomes very rapid, on the contrary, with fine wire, which, consequently, should be selected by preference in order to render the experiment as striking as possible. Wire of from one-tenth to two-tenths of a millimetre is perfectly adapted for a wheel of from eight to ten centimetres diameter. This transformation of calorific into electric and mechanical energy is the simplest that can be imagined.

Super-Sulphates and the Accumulator Theory of Darrieus.—This formed the subject of a paper which was read by Dr. Elbs at the recent annual meeting of the Deutsche Elektrochemische Gesellschaft at Frankfort-on-Main. The production of super-sulphates is, it is known, attended with difficulties. Dr. Elbs, of Frankfort, now claims to have devised a simple process by which these difficulties are removed. He has constructed an apparatus containing a platinum wire anode, the cathode being placed in a capillary above the anode in order to prevent the reduction of the super-sulphuric acid formed. An additional glass tube is fixed over the anode to allow the gases to escape. The electrolyte consists of sulphate impregnated with sulphuric acid. Soon after the current is applied the super-sulphates are detached in crystalline form. The solution, of course, retains a certain quantity of them. When heated with hydrochloric acid, chlorine is developed. Heating by itself evolves free oxygen. Herr Darrieus has given out a new theory, according to which the action in an accumulator proceeds from the presence of free super-sulphuric acid. Schoop declared himself to be of this opinion in the *Z. f. Elektrot. u. Elektrochemie*, 1894, Heft 9. On charging the accumulator super-sulphuric acid occurs at the one electrode, which converts the lead oxide and any lead sulphate into lead superoxide. As soon as this takes place, the resulting super-sulphuric acid decompounds into ordinary sulphuric acid and oxygen, which escape as gas, indicating that the charging of the superoxide electrode is completed. At the negative plate a reduction of the lead sulphate to spongy lead takes place, and when this is done occlusion of small quantities of hydrogen through the spongy lead occurs. Finally, the hydrogen appears as free gas, showing that the charging is concluded. When discharging, the occluded hydrogen is first oxidised to water, and the super-sulphuric acid present is reduced to ordinary sulphuric acid. The primarily increased E.M.F. of the accumulator corresponds to this procedure. Thereafter the oxidation of a part of the spongy lead on the negative plate into lead suboxide is completed, the suboxide at the same time being decomposed by the electrolyte into metallic lead and lead sulphate. On the positive plate lead superoxide is transformed into lower degrees of oxidation, which, with sulphuric acid, in course of time are partially changed into lead sulphate. This latter sulphatisation is the product of the combination PbO_2, PbO, H_2SO_4, and results, as is known, in the spontaneous discharge of the positive plate. This only ceases when there is no more lead superoxide present, and explains why superoxide electrodes can be completely transformed into lead sulphate. Because, Dr. Elbs states, Herr Darrieus examined in detail the causes of the gradual decomposition of the superoxide electrodes, he came to the above-named conclusions. Dr. Elbs argues, however, that this is not the case, and he points to the following experiment: If to super-sulphate of ammonium be added a lead salt—say acetate of lead—upon heating, lead sulphate together with lead superoxide is evolved. This reaction does not, however, take place in acid solution. It must rather be neutral or weakly alkaline. Now, free sulphuric acid is in the accumulators. The lead superoxide cannot therefore owe its inception to the super-sulphuric acid. A further experiment with super-sulphuric acid may be mentioned. If the solution of ammonium persulphate be combined with a lead salt and filtered from the precipitate, super-sulphate of lead is found in solution, which, upon heating, decomposes, lead superoxide being formed. These experiments, Dr. Elbs says, show that the super-sulphuric acid has nothing to do with the action of the accumulator.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 91.)

INTERVIEW WITH MR. C. E. L. BROWN.

In my quest for original information on the methods and successes of electrical engineers in Switzerland, I reached Baden and wended my way to the works of Messrs. Brown, Boveri, and Co. The commissionaire at the entrance informed me as he conducted me to the waiting-room that Mr. Brown was in, and I received a very cordial welcome from that gentleman, who wished to show me over his works at once, but I persuaded him to answer a few queries first. I tackled him on the alternating-current motor question.

C. E. L. BROWN.

"You, Mr. Brown," I said, "have had more to do with the construction of alternating-current motors than any engineer in Europe, and I should like to know by what processes you have reached your present stage of perfection."

"I commenced," he replied, "in 1890, a year before the opening of the Frankfort Exhibition, and then built simultaneously a two-phase and a three-phase motor for experimental purposes. It was stated that the three-phase motor only would be successful, but I found that the two gave equally good results as regards output, power, and efficiency. In fact, even now we use exactly the same patterns for two-phase and three-phase machines of the same output, and only vary the winding arrangements."

"What was the next step in your investigations, Mr. Brown?"

"I found accidentally that the multiphase motor, if started, would run even if one of the wires was disconnected, although in speed it was not absolutely synchronous with the supply. In fact, if the wire was removed while the motor was running over the half speed it continued increasing in speed up to its usual rate."

"But did you find the motor with the one circuit disconnected as powerful as before?"

"Of course, this was not to be expected, and we found that we could get about two-thirds of the work out of a single-phase motor that we could out of a multiphase machine of the same size. The efficiency, too, was considerably lower. These experiments led me to investigate the means of starting alternating-current motors on single-phase circuits, as I found that once started there was no difficulty in keeping them at work. I tried with self-induction, capacity, and resistance effects to obtain a difference of phase in starting between the current in the two windings of a motor, and after a long series of experiments I determined to devote my energies to the perfection of the capacity arrangement. I found that electrolytic cells had a large capacity if the solution was correctly chosen. We have now adopted the constructions as follows: a series of iron plates is fixed in a box arranged to form capacity and resistance in series, the solution surrounding the plates being a solution of water and soda, and with this arrangement we can easily obtain a difference of phase of about 90deg. between the self-induction and the capacity circuits."

"Have these water capacities been a success in practice?"

"At first we had difficulty with the containing vessels, which we used to make of wood, the trouble being that the solution soaked through and the reduction in capacity affected the starting of the motor. After that we tried stoneware containing vessels, but these it was difficult to obtain sufficiently uniform in shape. At length we have succeeded in obtaining an enamelled-iron containing vessel, which answers perfectly in every way, and enables our motors to be started without the slightest trouble."

"How do you account for the fact that alternating-current motors have not been more largely used in England?"

"The reason, in my opinion, is the great variation in the frequency employed at the various stations, combined with the fact that at high frequencies alternating-current motors are not so efficient. To illustrate this to you, I would remind you of the fact that the speed of the motor is a simple function of the number of poles and the frequency of supply. Hence, if high frequencies are used, you must either increase the number of poles in your motor, or else allow it to run at an abnormally high speed. It is an acknowledged fact that to make small motors with a large number of poles is both costly and inefficient, therefore the high-frequency alternating-current motor is not so good as one to be employed on our standard frequencies of from 40 to 50 complete cycles per second. A good comparison occurring to me is to state that it is, in my opinion, as absurd to make small motors with a large number of poles as it is to build a big direct-current dynamo with only two poles, or to build a small continuous-current dynamo of one or two horse-power with six or eight poles."

"You do not, then, approve of the design of large two-pole direct-current machines?"

"For outputs above 50 kilowatts I always make my machines four-pole or more, and I am sure that more economical and efficient designs are thus to be obtained."

"As regards the system of supply, what general rules do you follow?"

"In laying down plants where the main demand is for lighting with a few small motors as well, I always use single-phase; when the supply of power and light is approximately equal, I prefer the two-phase system, and, again, when the power supply much predominates, I always adopt three-phase

"And why do you make the last-mentioned distinction?"

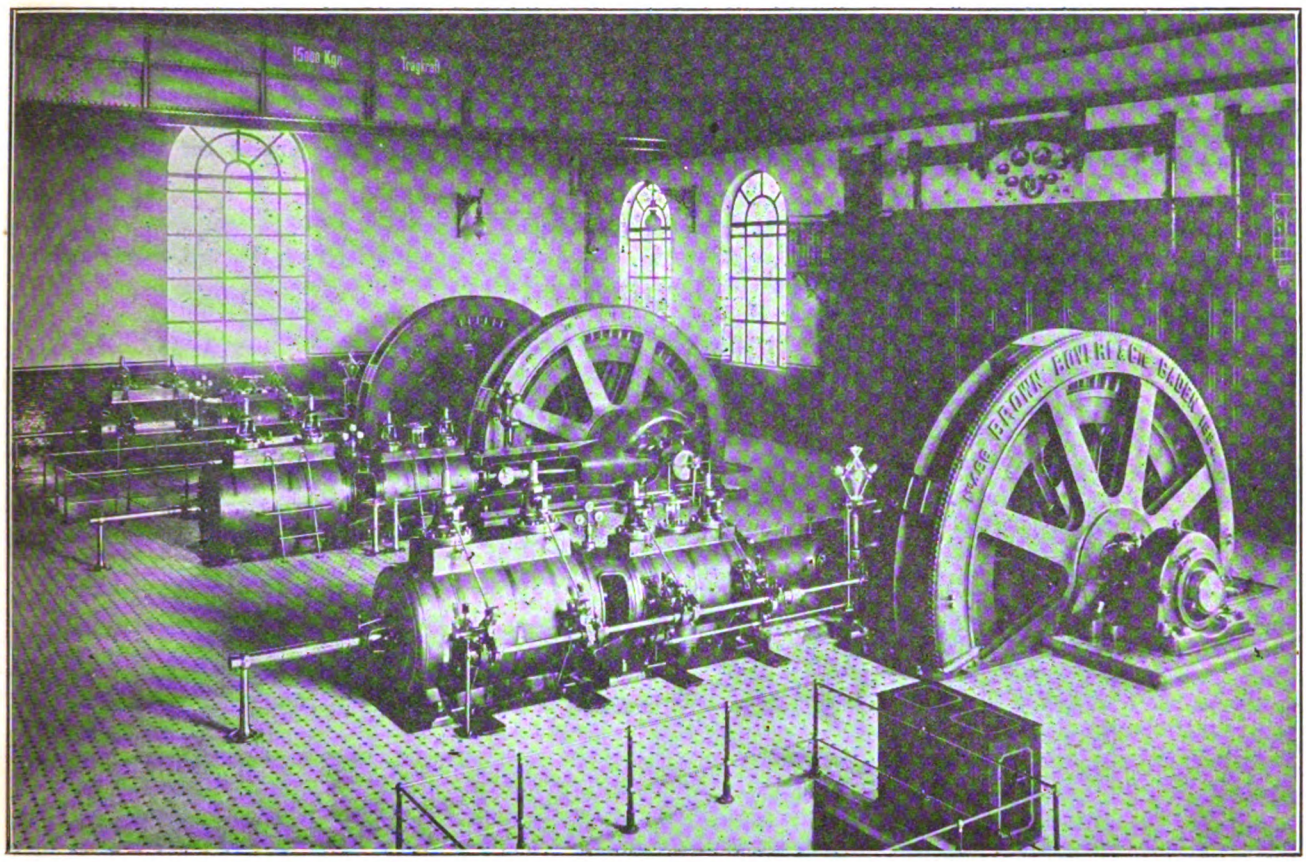
"Because, as you will readily see, with a three-phase system of distribution each of the three circuits is dependent on the other two, unless the load is arranged between the terminals and a fourth wire connected to the neutral point of the generator windings; whereas a well-designed two-phase alternator with a three or four wire circuit may be loaded fully in one phase without materially affecting the tension in the other. Thus you will see that on account of the complications involved in the former system the latter is much to be preferred."

"Up to what pressure do you wind your alternators?"

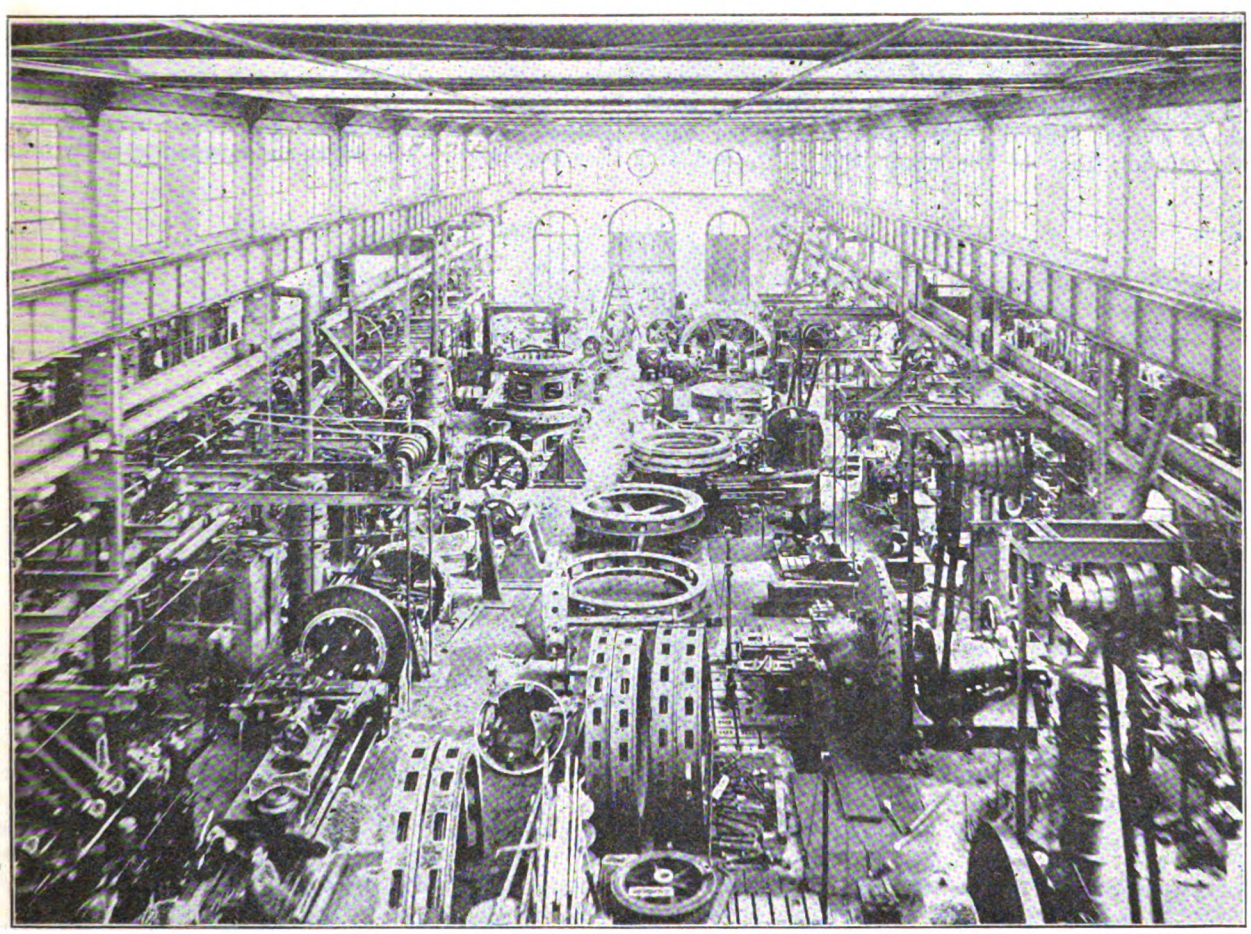
"Up to 5,000 volts we always generate the pressure in

Digitized by Google

the alternator, and this pressure is sufficient for transmission work up to 10 miles. At the receiving stations we transform down for small motors, but I have built a 110-h.p. motor for 5,000 volts, which has now been running for over a year, and am at present building one 100-h.p. and two 65-h.p. motors to work direct at this tension, besides a large number of other sizes for 1,000, 2,000, and 3,000 volts."



Installation Work of Messrs. Brown, Boveri, and Co.



Large Machine Bay at the Works of Messrs. Brown, Boveri, and Co., Baden.

Digitized by Google

"With the large transmission work that you have in hand, what do you find the mean output of your machines to be?"

"The average output of the machines supplied last year was over 100 h.p. each, and I see no reason why this figure should not be exceeded during 1895."

"I can see," I remarked, "that the large amount of available water power in Switzerland gives you great advantages for electrical transmission; but I should like to ask you what you find the average cost of a water-power plant where no large engineering works have to be constructed."

"I should state the average cost of turbines and water-works to be from 800f. to 1,000f. (£32 to £40) per horse-power output; that of the generating plant, including alternators, switchboards, etc., 100f. (£4) per horse-power; and the line, which is, of course, a very variable item, I should put at from 50f. to 100f. (£2 to £4) per horse-power. In fact, the whole cost you may take as averaging 1,100f. (£44) per horse-power."

"I see, Mr. Brown," I ventured in conclusion, "that this amounts to about £60 per kilowatt output, which is approximately the cost of a complete steam plant in England."

"Of course," he hastened to explain, "it is in the annual upkeep that we gain over a steam plant as in the inaccessible spots in which we can place our electrical generating plants the water power is exceedingly cheap."

MESSRS. BROWN AND BOVERI'S WORKS.

The walk through these works, under the personal guidance of Mr. C. E. L. Brown, was most interesting, both on account of the large size of the machines under manufacture and also to the great care shown in the various details. The works, which were only started some four years ago, have grown most rapidly, and when I visited them a new addition was almost ready to receive the machinery. The works are maintained solely on work on order, nothing being made for stock. At the time of my visit the orders on the books amounted to an aggregate output of 30,000 horse-power, of which about one-third was for continuous-current machines. The whole of the power required is obtained from a water-power station, situated on the river about a mile away. The transmission pressure is 1,000 volts, and the same station also supplies light to the town of Baden. The method of driving the machinery varies with the size of the tools.

Motor with Armature and Field Wound on the Brown Patent Cylinder System.

All the large tools have an independent two-phase motor to drive them. In this they are independent of the rest of the works, and this also allows of them being placed with their axis at right angles to the sides of the bay. This can be seen in the illustration of the heavy machinery department, and the arrangement greatly facilitates the transport and attachment of the work. Owing to the works being specially designed for dynamo and alternator work, a large number of special machine tools have been laid down, which greatly assist in the rapid execution of the orders.

The Brown system of armature connection is of special interest. By it all the arms and connections are kept on the same cylindrical surface area, then as the conductor forms the connection the number of soldered joints is reduced in the ratio of about 5 to 2, as compared with the usual English practice. Two examples of this method of winding are shown in the illustrations.

COUNTY BOROUGH OF SALFORD ELECTRIC LIGHT WORKS.

The electric light works of the Salford Corporation, situated in Walness-road, Lower Broughton, were formally opened last week by Mr. Councillor R. Holland, chairman of the Gas and Electric Lighting Committee, in the presence of the mayor (Mr. Alderman Mottram), the mayoress, Mrs. Holland, and other ladies, the town clerk and the members of the Council, the gas engineer (Mr. Shonbridge), the superintendent of the electric light station (Mr. Turner), the borough engineer (Mr. Corbett), the borough analyst (Mr. J. Carter Bell), and others.

Mr. Councillor HOLLAND, in handing over the works to the Mayor on behalf of the Corporation, said that in 1892 the Council decided to provide electric light for the borough, and directed the Gas Committee to take the necessary steps to carry out their wishes. The Council at that time did not intend to spend more than £15,000 upon the installation, but from the replies to a circular which the committee sent to probable consumers, it was evident that this sum would be inadequate, and on this being reported to the Council, they agreed to extend the scheme to the extent of £30,000, and to apply to the Local Government Board for power to borrow £50,000 to cover the first cost of the installation, and to meet future extensions. The amount actually paid to the present time is £29,206, and the balances due to the various contractors on the expiration of the period of maintenance, will increase the expenditure to £34,338. The committee engaged Messrs. Kincaid, Waller, and Manville, electrical engineers, of 29, Great George-street, Westminster, to devise a scheme of supply and prepare the necessary drawings and specifications. The committee have adopted the high-pressure alternating system, by which the current is supplied at a pressure of 3,000 volts through concentric copper cables, insulated with special impregnated fibrous compound laid in cast-iron pipes. This pressure is reduced by transformers at consumers' premises to about 100 volts. There are three sets of engines and dynamos at the generating station, each set capable of supplying 2,500 8-c.p. lamps alight at one time, or to 2,800 lamps connected to the mains, it being found that only about 60 per cent. of the lamps connected are alight at the same time. As it is necessary to keep one of the sets of plant in reserve, the producing power of the station is equal to supplying 8,300 8-c.p. lamps connected to the mains. The cables have been constructed to supply 17,000 8-c.p. lamps, and will therefore meet the requirements for a considerable time. The committee purchased a plot of land, on which to build the generating station, adjoining the River Irwell, so that the water from the river could be used for the condensing engines which have been adopted. The land acquired is large enough to allow of any extension of the works that may be required ultimately. The buildings, which have been erected by Mr. Samuel Warburton, of Manchester, for the sum of £6,600, consist of an engine-room, faced inside with glazed bricks, a boiler-room, pump-room, workmen's messroom, stores, offices,

Digitized by Google

switchroom, and testroom. The buildings are faced externally with Ruabon pressed bricks, combined with terra-cotta, and have a very handsome appearance. There

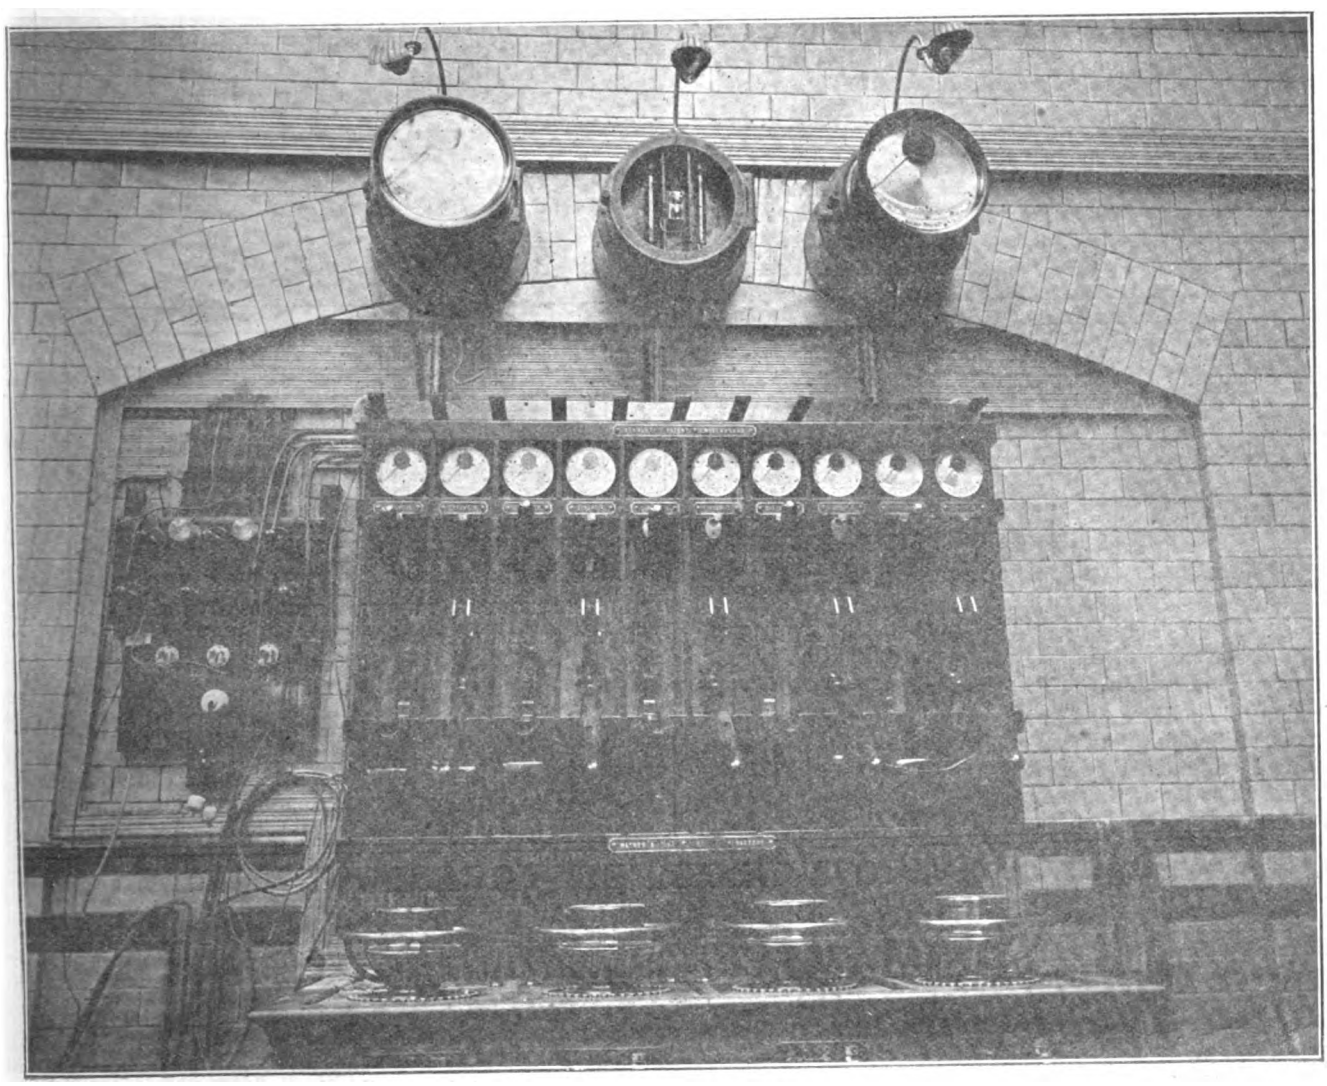
Salford Central Station—Boiler Battery.

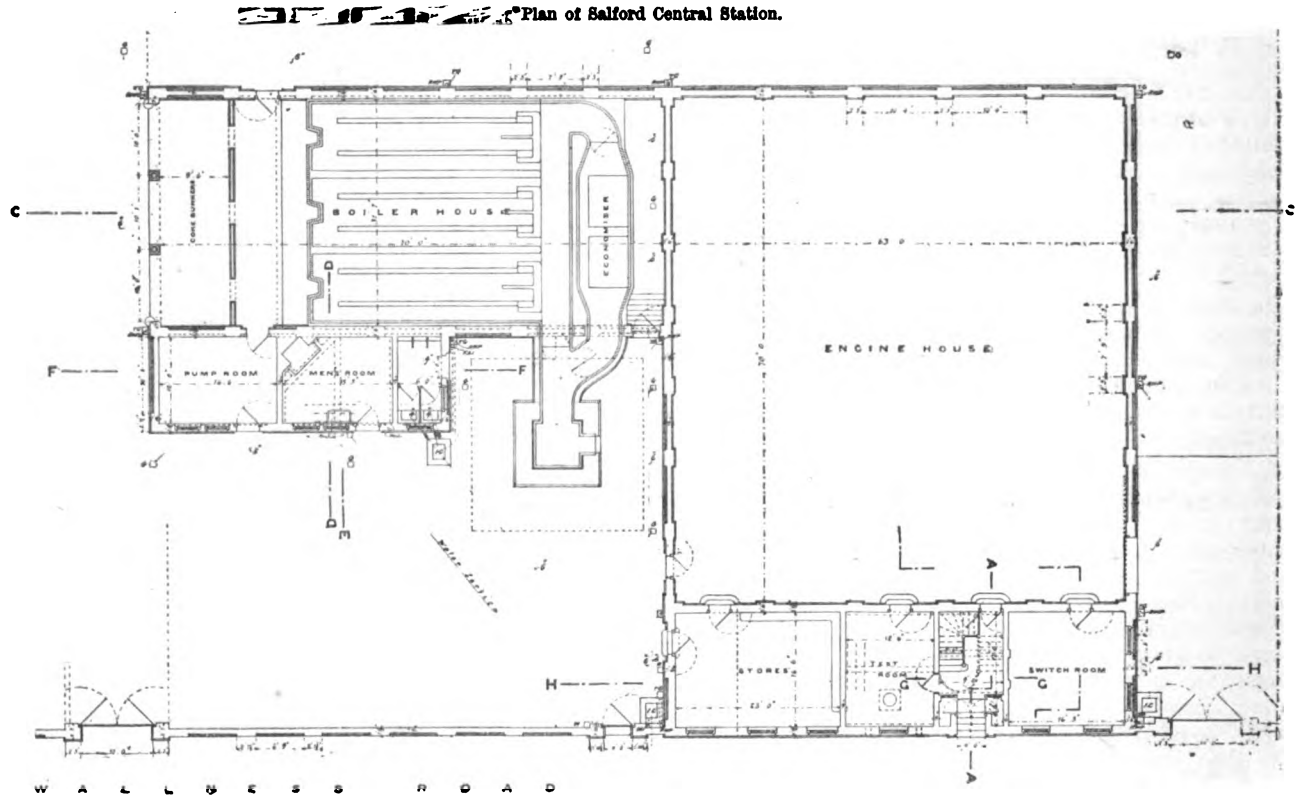


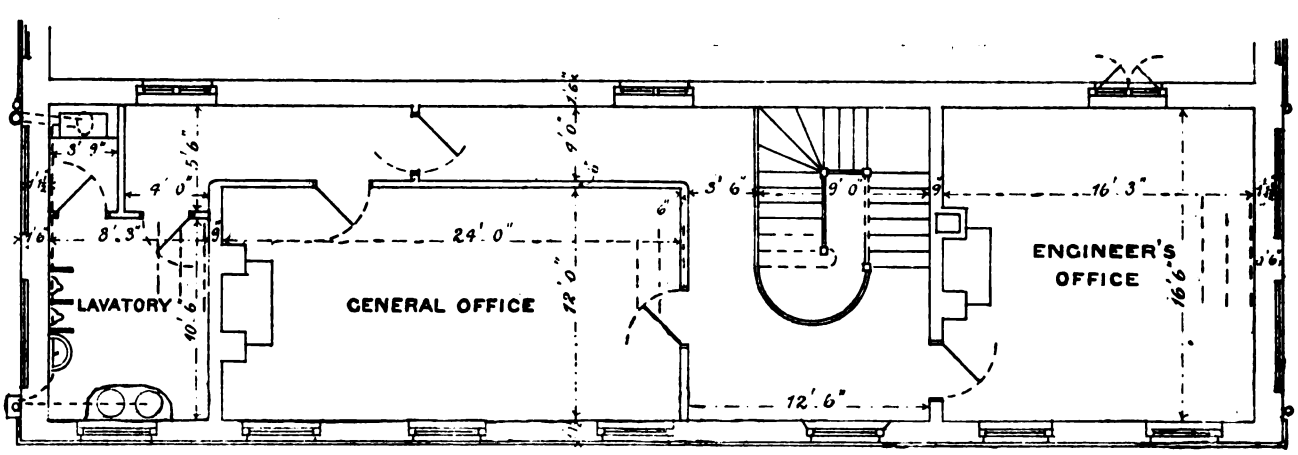
Salford Central Station—Switchboard.

Digitized by Google

contract being £3,150. There are three Lancashire steel boilers, fitted with mechanical stoking appliances, economisers, etc. They are intended to work at 160lb. pressure, and were supplied by Messrs. Tinkers, Limited, Hyde, at a cost of £3,704. The fuel to be used in them is coke from the Corporation gasworks. From trials that have been made, it has been found that not only has gas coke the great advantage of being a clean smokeless fuel, but it is a very economical one for steam-boilers. The mains are laid in three circuits as follows: Circuit No. 1—from the generating station, passing through Camp-street, Fenney-street, Bury New-road, as far as Mayfield-road, with two branches, one along Singleton-road and Upper Park-road, the other along Park-street and Old Hall-road. Circuit No. 2—from the station along Lower Broughton-road, Broughton-road, Blackfriars-street, as ar as the

Plan of Salford Central Station.





First Floor Offices, Salford Station.

bridge, Chapel-street, The Crescent, and Broad-street, as far as Frederick-street. Circuit No. 3—from the station along Irwell-road, Frederick-street, Broad-street, and Eccles Old-road, as far as Claremont-road. These circuits will be extended from time to time as the demand for current increases until they are spread over the whole borough. At the present time the Corporation have 19 customers, who have altogether about 1,000 lamps, and there are applications from others for a supply for about 500 additional lamps. It is anticipated that a great many more applications will be received when the lighting season commences. The charge for current at present is 7d. per unit, but the committee intend to reduce this as soon as they are able to do so.

The CHAIRMAN said that although the contractors had taken a great deal more time than was expected in completing their work, great pains had been taken to make every part substantial and satisfactory in every way, and he felt that the Corporation had a work thoroughly well equipped and of which they might be proud. He hoped the results obtained from it would be equally satisfactory, and be a source of profit to the ratepayers. He had much pleasure in informing the mayor that the work entrusted to the Gas Committee by the Council was now completed, and everything ready for supplying current to the consumers.

The MAYOR said it gave the mayoress and himself great pleasure to be present and to take part in the inauguration of the works. The electric light undertaking was a most important addition to the responsibilities of the Corporation, and one that he felt sure would prove a source of great benefit to the ratepayers. As an engineer, he had taken great interest in the works, and had watched them carefully whilst in process of erection. He was satisfied that they had a most excellent installation, creditable alike to the contractor and to the Corporation. The boilers, engines, and dynamos were first rate of their kind, and would bear comparison with any others in the country. The Council was much indebted to Mr. Holland, and the members of the Gas and Electric Lighting Committee, for the pains they had taken in carrying out the work entrusted to them. He had pleasure in asking Mrs. Holland to start the engines and turn on the current.

Mrs. HOLLAND then proceeded to start the engines and switched on the current, and amid the cheers of those present the engine-room and other parts of the station were instantly brilliantly illuminated.

ELECTRICITY IN MINING WORK.

BY T. B. A. CLARKE, B.A.

No department of our industries perhaps promises more scope for the development of electric appliances than coal-mining. In almost every mine the problem arises how to convey energy to a distant point. The road by which this point is reached is in very many cases tortuous, narrow, and low; and these considerations make it of prime importance that the apparatus by which the energy is conveyed should be flexible, easily repaired, and especially take up little room. The electric wire or cable satisfies all these conditions in a very remarkable and unique manner. Even if electricity were the least efficient, instead of being, as it is, the most efficient means of transmitting energy, it would, for the reason above stated, be a very formidable competitor of any transmission system now in vogue.

It is impossible in the course of a short article to examine in detail how the various difficulties inherent in electric mining work are met. I propose to consider more fully in further articles the following subjects: (1) electric lighting of collieries, including surface works, underground roads, and portable electric safety lamps; (2) electric pumping, main, dip, and sinking; (3) electric haulage by endless rope, main and tail rope, and locomotive; (4) electricity at the coal face, coal cutting, drilling, and blasting.

In these articles accounts will be given of the most important installations at work, accompanied by tests, results, criticisms, and comparisons with other means of transmitting power. In this article I propose to examine the general conditions which limit the use of electricity in our mines.

1. *Danger of Exploding Inflammable Gas.*—This is the most important matter to be considered, and it is one about which a great deal of misconception exists. Of course, the ventilation of most of our mines nowadays is good enough to prevent any accumulation of gas in a working face. Gas, however, is constantly being given off and swept away by the air current, but there is a danger to which some seams of coal are particularly liable—namely, a sudden outburst of gas which the air current cannot dissipate for a considerable time, sometimes several days. The ingenuity of electrical engineers has for a considerable time been exercised in providing electric apparatus which shall work with safety in the most inflammable mixtures of gas and air. It will be well to examine these somewhat in detail, and see how they answer the purpose for which they were designed.

To consider the case of the motor first. A well-designed continuous-current motor working within its load and in good condition should not spark appreciably. An accident may easily occur, however, which may set up sparking at the brushes and cause an explosion. It has been clearly shown, by experiments at the Aldwarke Collieries of Messrs. John Brown and Co., that excessive sparking will explode gas, hence the obvious precaution is to enclose the brushes and commutator in a case, which either must be gastight or have any openings covered with gauze, as in the miners' safety lamp. The gastight case renders the armature and commutator entirely safe, and if the motor is of the iron-clad type (Lahmeyer) the field-magnet windings will be well protected against any fall of roof which may occur. The objections to this method are, of course, the difficulty of dissipating the heat from the armature coils and commutator, and of giving proper attention to the position of the brushes. The obvious deduction from this is to be sure and have your motors of ample power. In that case neither heating nor sparking will give trouble. The method of having openings in the casing covered with gauze cannot be too strongly condemned. It is a mere plausible travesty on the safety lamp. Suppose, for instance, that the casing is charged full of gas, it is, of course, exploded; the gauze, or even the whole casing, would be blown off, the armature would be burnt, and the flame would inevitably explode the gas inside. In the case of a safety lamp the flame is extinguished by an explosion of gas inside the lamp; in the case of a motor it would not be, and hence the gauze casing is no protection at all. This difficulty is now being attacked by some manufacturers in a radically different manner—namely, by using motors driven by single, double, or three-phase alternating currents, and dispensing altogether with commutator and brushes. This is an interesting departure, and may give good results in time. At present, however, there is not sufficient data to go upon to pronounce definitely whether the continuous-current motor is in any danger of becoming obsolete. For myself, I think not. The Frankfort-Lauffen plant and others since show plainly that good and efficient work can be done by motors of this type, but it is certainly premature to say that these motors could successfully cope with all the various classes of work to which continuous-current motors are put in a coal mine. The other day I examined carefully a number of such machines which an enterprising electrician hopes to put on the market to the discomfiture of the continuous-current machine in mining work. The opinion I came to was that while for some classes of work they would be quite suitable, for others, and those cases when gas was most likely to be met, they were quite unsuitable. However, they certainly dispose of the sparking difficulty, and were that all that had to be faced they would ostensibly be a satisfactory solution of the question.

Another point, however, remains, and that, in my opinion, is of far greater importance than the motor question. I mean the damage to cables, connections, and switches. The contact of the cores of two cables, or the severance of either, means a momentary spark or flame. It is, of course, argued that to have an explosion two conditions must be simultaneously fulfilled: firstly, damage must be done to the cables; secondly, gas must be present at that moment. If the cables are carried along a road swept by the intake air the danger is small, but still it exists, and many managers are unwilling to add one more risk to the list of those which already exist in a mine. The most prominent attempt to meet this difficulty is by having your cable surrounded spirally by, and insulated from, a thin wire, which is connected separately to a small fuse on the switchboard on the surface. In case the cables are torn down and broken, the thin spiral wire stretches, and ultimately, on the severance of the main wires, carries the whole current. This blows the small fuse at the top, and the current is interrupted without spark. So far so good. Accidents to cables happen, however, in many different ways from this, and if both cables were jammed together violently, say, by a load of trucks, a short-circuit would occur, which would undoubtedly cause a momentary flame of intense heat. A short time ago I examined an installation down a fiery pit where these cables were used, and the manager told me that twice in one month such an accident as that stated above had occurred. In both cases an intense momentary flame had been the result.

The safest way to lay cables in a fiery mine is to run them underground in iron pipes. Of course, this is very costly, and does away with many of the advantages of electricity. Trouble may also ensue from the floor rising, if soft, and breaking the pipes. The question is a most serious one, affecting as it does the lives of everyone in the mine, and any electrician installing such work in fiery mines incurs a very heavy moral responsibility. My opinion is, that where the pit is fiery electricity is not suitable owing to the great risk involved. To make myself perfectly clear, I would explain that I do not consider it safe to run cables through any part of a mine where there is liable to be either an accumulation of gas or an outburst. Happily, however, such mines do not preponderate, and there is ample scope for the manufacturer of electric machinery in those well-ventilated and moderately gassy seams without trying to push his wares into places where grave risk is incurred and tragical results by no means improbable. Should any such mishap occur, the check to the progress of electricity in mines would be enormous. A hard-and-fast rule would be laid down by mine inspectors as to the use of electricity. Electric plant would be enhanced in cost by the necessity of providing a number of precautions superfluous if the place is fit for electricity, and useless certainly if the place is unfit.

THE GLASGOW TRAMWAYS.

Municipal action, in whatever direction it takes, is watched with considerable interest, because upon it to a large extent depends the welfare of the inhabitants under the municipalities. What, then, are the main features of municipal work? First, we have questions of morality under the supervision of police and magistrates, but the consideration of these will not detain us. Then we have the sanitary problems, to be solved by the engineer and officer of health. These, again, need not detain us.

Perhaps the distribution of water will be considered a sanitary problem. Whatever opinions may be held upon other questions to be mentioned below, we imagine there are few who will differ as to the advisability of the personal and properly safeguarding and the sanitary works being under the control of the local authority. Further, there will be no divergence of opinion about the construction and maintenance of streets being under that control, and, so far as we are concerned, we have always advocated the control by the local authority of the artificial light, whether it be gas or electricity. We are, however, not so certain when the question comes to haulage, whether on tramways, railways, or streets. In this article, however, we shall restrict our remarks to tramway working. Having agreed that the roads and streets must be under the control of the authority, it becomes a delicate question how far that authority should work the vehicular traffic. Viewed from the standpoint of initiation of reforms, the municipal control is out of question. It is difficult to conceive a municipality being in advance of its time, and yet improvements are generally introduced by men in advance of their fellows. Would any municipality have of its own initiation adopted the electric light without the push and enterprise of such men as Jablochkoff? They usually want to see first that a new development is practical; they do not want to experiment, but to use the costly experimental results of others. This part of the subject again divides itself into two phases, those developments that the inhabitants must participate in and those that they may. Water, light, and air must be had, and the veriest dolt cannot but see that nothing short of the best can ever lead an authority to rest. The ratepayers will not look too closely into an expenditure undertaken to ensure better water, light, or air, but they will look with suspicion upon a suggestion made in the earlier stages of development of some means of accelerating or bettering locomotion. So much for the initiative question, but the matter is simplified when it comes to the use and control of something proved. Better, quicker, cheaper means of moving from one part of a town to another must benefit the community generally, so that tramways having been proved in these directions may possibly come within those undertakings that should be controlled by the local authority. Of course, another strong argument to favour this view is that the roads and streets can be maintained in better repair when the controlling authority is undivided. A still stronger argument than has yet been mentioned is a financial one, and this is one that appeals very forcibly to the

Digitized by Google

ratepayers. The working of the tramways may be a big financial success, and some considerable relief to the rates may be obtained from the enterprise. To us this argument seems of the weakest, for whatever can be advanced in its favour may also be advanced in favour of every other business in the town, be it the baker's, grocer's, or rag and bone merchant's. Let us, however, see what Glasgow has done as regards its tramways. The abstract gives place here to the concrete. Glasgow owns the tramways, and, after a fairly long experience of leasing the working, took the sole control of the working into its own hands from July 1, 1894. The income for eleven months' working, the financial year for the city ending May 31, is £226,414. 3s. 4d., the total expenditure, including interest, the maintenance and renewal of permanent way, buildings, machinery, plant, horses, harness, rolling-stock, and equipments, is £202,209. 9s. 2d., leaving a credit balance of £24,204. 14s. 2d. This is an excellent result when the period of working is considered, and the enormous difficulties in taking over and starting, as it were *de novo*, on a given day are examined. We wonder that the balance was not adverse. The capital account was £552,956, now depreciated from credit balance to £543,762. The whole text, sermon, and moral may be summed up in a few words. Here is one of the largest and most enterprising cities in the kingdom investing over half a million in a business closely connected with the business welfare of the community, successful from the first moment of its undertaking and promising greater success in the future. Shall its example be followed, and if followed, will the imitators still go on the old lines of horse traction, or will they admit that electric traction has claims that indicate it would be still more successful than the older system. The average cost per train mile is 9·34d., and 1·12d. represents the credit balance of receipts over expenditure per train mile. The mileage for the eleven months has been 5,192,031; the passengers carried 57,104,647; the average receipts per mile being 10·26d. It will be seen that the success is due to the enormous traffic, and this is no doubt due to the cheapness and excellency of the service.

REFUSE DESTRUCTION AS APPLIED TO ELECTRIC LIGHTING PURPOSES *

BY E. MANVILLE, M.I.E.E.

The question of the destruction of ashbin refuse is one that has, as you are well aware, occupied the attention of local authorities for a good many years past, and during the past three years the attention given to the subject has materially increased, owing, probably, in the first place, to the difficulty of finding suitable tips at which to deposit the refuse; secondly, to the increasing cost of the disposal of refuse; and, thirdly, to the various opinions that have been expressed as to the amount of available energy that can be derived from the refuse if burned under proper conditions. This last reason has stimulated the energies of local authorities, but I think I may say that the necessity of disposing of it in such a manner as to in no way endanger the health or comfort of the ratepayers has at least equally assisted in the most mature consideration being given to its disposal in a sanitary manner, even if such disposal has to be accomplished at a cost exceeding the older-fashioned methods. Fortunately, however, excepting in those places bordering on the sea coast, and even in many of these, the cost of the disposition of ashbin refuse in the most sanitary manner at present known is less than the carting and barging away and tipping it in suitable or unsuitable spots. I allude, of course, to the perfect cremation of the ashbin refuse in what are commonly known as dust destructors. If I were to attempt in the short space of the 20 minutes allowed me to describe the various methods and systems on which dust destructors have been constructed, I could do but very scant justice to the subject; and I propose, therefore, chiefly to explain to you a system of dust destructors and boilers at present being erected for the Vestry of Shoreditch, in London, in which the most desirable methods of effectively and absolutely disposing of the ashbin refuse have been combined with the most efficient conceivable arrangements for the production of energy from the heat evolved, without detriment to the thorough combustion of the refuse.

The progress of the design of the dust destructor has certainly been one of slow evolution. In the first days of the design of these furnaces little seems to have been considered beyond the means of burning, or partially burning, the refuse, without any consideration as to the treatment being carried on in a scientific manner; and doubtless this has had a great deal to do with the prejudice that still in many places exists as to the presence of such an installation within a large city or town. Had destructor furnaces been from the very commencement so designed that all the gases produced in the heating and burning of the refuse were thoroughly and completely burned, but little prejudice would probably now exist.

To attain these results, the facts to be borne in mind by designers of destructors are simple. The gases produced by the destructive distillation of ashbin refuse must, to ensure their thorough combustion, be raised to a temperature of at least 1,200deg. F., and to ensure this minimum temperature the mean temperature should not be much less than 1,800deg. F., so that during the operations of clinkering, etc., the temperature of the interior of the furnaces may not fall below the specified minimum of 1,200deg. F. In some designs of destructor furnaces, where the rate of burning of refuse is such that temperatures of only 800deg. or 1,000deg. F. are attained in the destructor cells, this end is provided for by the addition of a secondary fire, over which all the products of combustion from the burning refuse are passed, and which during their passage through this secondary furnace are, by virtue of its heat, raised to that minimum temperature. On the other hand, of late it has become a common practice to burn the refuse under a forced draught at a more rapid rate than previously, and by so doing to raise the temperature of the destructor furnaces themselves to a temperature often attaining, and even exceeding, 2,000deg. F. Designs have been adopted in which all the gases produced in the furnaces are made to pass through the hottest portion of them, in order to ensure their being raised to the maximum temperature before leaving the destructor cells.

This method has proved itself eminently satisfactory so long as normal conditions are maintained in the quality of the refuse to be burned; but I think it is improbable that in any place every load of refuse could be absolutely relied on to contain nothing of a character that might prevent this high temperature being attained, and therefore I believe that, especially in small ranges of destructor cells, means should be provided for adding a secondary fire, even if it be only used for an hour or two occasionally, when the refuse is of a very doubtful description. Proper design and provision of this kind having been made, there can be, I think, no doubt in the minds of those responsible for the erection of dust destructors as to the certainty of complete combustion of the gases taking place, and the entire absence of anything in the shape of a nuisance to the surrounding neighbourhood.

The calorific value of burning refuse has so often been called in question, and such varying statements have been made as to results so far achieved that there is little wonder at the incredulity of many local authorities as to the refuse having any value worth talking about from a steam-raising

* Paper read before the Hull Congress of the British Institute of Public Health.

Digitized by Google

point of view. Some of these contradictory statements have been made from sheer ignorance on the part of those who make them, and others on account of the conditions under which the steam raising has been performed, which conditions have involved the loss of a great deal of the heat from the products of combustion before the boilers are reached, and then the complete insufficiency of the boiler-heating surface on which the heated gases act. I have myself heard practical users of dust destructors state that but an extremely small amount of steam can be hoped to be produced with their dust destructor, and therefore with dust destructors in general. Now no doubt the calorific value of ashbin refuse varies in every district according to the nature of the district and the season of the year, but after making due allowance for such differences as might exist under these conditions, some of these statements still seem to be entirely ridiculous to me and to those who, like me, have taken the trouble to ascertain what may be attained in the way of steam raising with ashbin refuse. I have endeavoured in such cases to find out the reasons that have induced these gentlemen to place such discouraging figures upon the calorific value of their ashbin refuse, and I have invariably found that the cause was due to the mixture of foreign substances with the refuse collected from the ashbins. In one prominent case, in which a gentleman well known in connection with dust destructors has from time to time stated that in his belief no such horse power as talked about by others could be obtained from ashbin refuse, I found that his ashbin refuse was enormously diluted with street sweepings before it was burned in his destructor. Of course, it follows that if matter of an entirely incombustible nature is mixed with—if I may term it—pure ashbin refuse, the calorific value of the ashbin refuse may be so reduced that it may be entirely worthless as a steam producer, and I do think it most desirable that where the unusual conditions of the admixture of foreign substances with the ashbin refuse occur, those who talk of the steam-raising powers of ashbin refuse under these conditions should be always careful to mention that it is so mixed. I refer strongly to this point, since several local authorities who, to my personal knowledge, might have erected dust destructors and utilised the steam raised by the combustion of the ashbin refuse, have been so discouraged by these contrary and apparently inexplicable statements that they have abandoned altogether the consideration of a destructor scheme.

As long ago as 1892 the Vestry of St. Leonard, Shoreditch, in London, having in view the erection both of a central electric supply station and of a dust destructor, I, in my capacity of their adviser, strongly recommended them to combine the two schemes. A great deal of careful investigation was carried out on their behalf to ascertain what power might reasonably be expected as obtainable from the burning of their ashbin refuse, and as a result of this investigation I felt enabled to assure them that all the steam required for the estimated electrical output likely in the first instance might be obtained from a properly designed dust destructor. In arriving at this opinion I experimented on a large scale with samples of ashbin refuse collected from various parts of Shoreditch, at a season of the year when household fires were not much in use, and I found it was extremely rich in carbon. Indeed, when the unsorted refuse was burned directly in a boiler, it evaporated as much as 3lb. of water from and at 212deg. F., and my opinion that the steam required could be obtained from the burning of this refuse in a properly designed arrangement of destructor cells and boilers, was founded on the supposition that only about one-third of the calorific value of the refuse would be utilised in the boilers, after due allowance had been made for the complete and perfect combustion of the ashbin refuse and its gases.

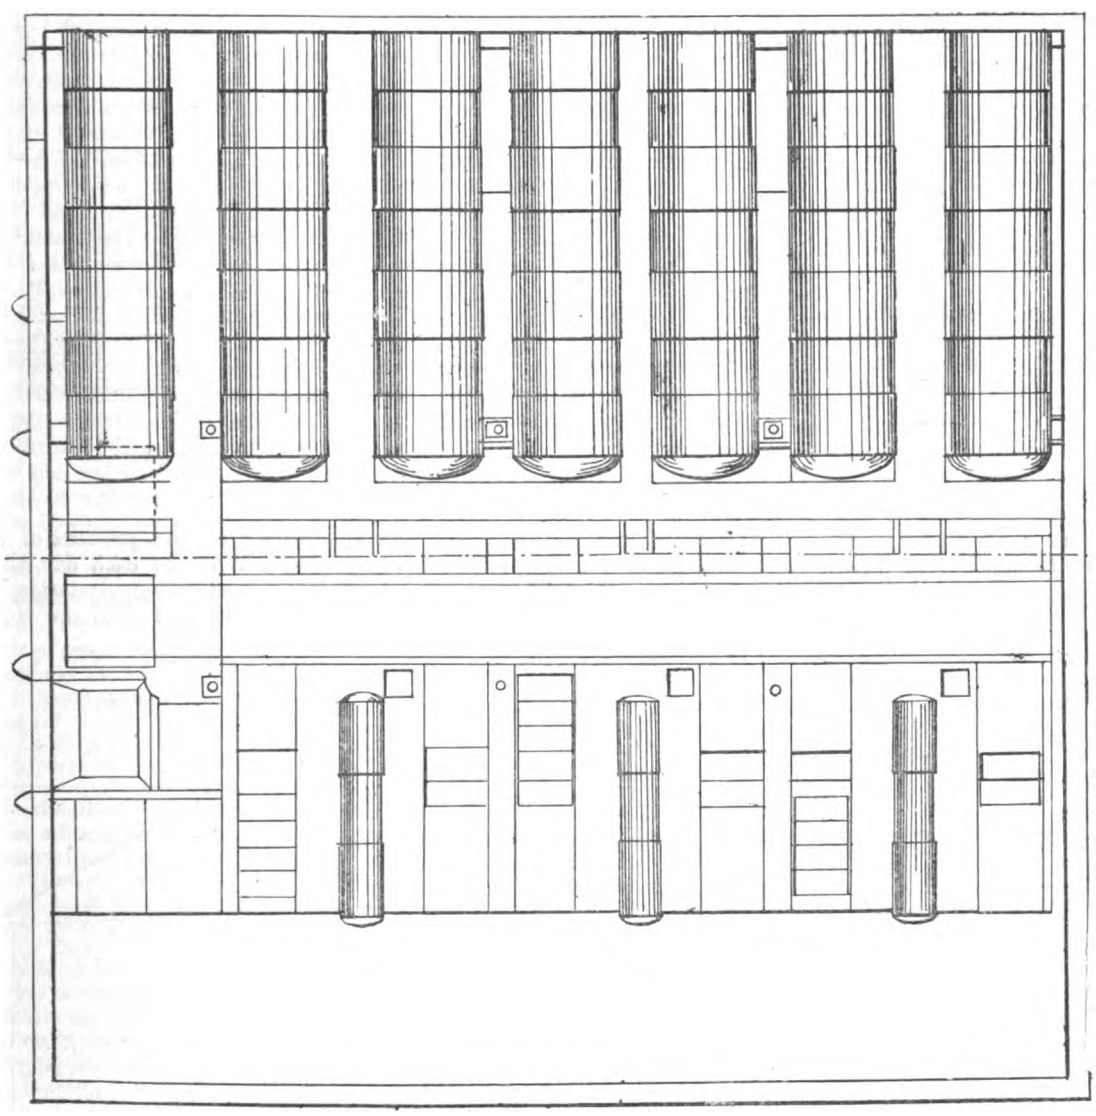
The Vestry thereupon resolved that such a combination should be erected forthwith. It took some time to secure a suitable site for these buildings and other municipal buildings the Vestry wished to erect at the same time; and about four months ago I was enabled to proceed with the plans of the arrangement originally proposed by me. A number of tenders were received for carrying these plans into effect, and ultimately the contract was awarded to Messrs. Manlove, Alliott, and Co., of Nottingham, on the following basis, and the works are now in process of erection. They consist essentially of a destructor-house in which is arranged a range of destructor furnaces, 12 in number, in two banks of six each placed back to back, with a working floor in between. The destructor cells are arranged a pair on each side of a Babcock and Willcox boiler, there being thus in all six boilers. Each of these boilers has a heating surface of about 1,400 square feet, and the pair of cells on each side of it are arranged to discharge their products of combustion under the boiler tubes immediately above the level of the firebars, these latter being left in the boiler, together with the fire-doors, in the same manner as if the boiler were being erected without the accompaniment of dust-destructor cells. Each cell is arranged with double flues, one leading to the boiler, as aforesaid, and the other direct into the main flues. Each destructor has a grate area of 27 square feet. The main flues are arranged above the floor level and underneath the working floor, and are in duplicate, each boiler and cell being able to discharge its gases into either or both of the main flues. This arrangement of duplicate flues is essential in the combination of a dust destructor with an electric lighting station, as the dust carried over with the products of combustion from the cells into the main flue must be removed at moderately frequent intervals, whilst the working of the main flues can never be discontinued owing to the necessity of continuous steaming of the boiler, and this duplicate arrangement of flues enables one flue at a time to be cleaned out, the products of combustion of all the boilers and all the cells being taken into the remaining flue during that time. At the end of the main flues is placed a chamber, which for the present will serve the purpose of a dust-depositing chamber, but may in the future, if found desirable, be divided up to contain an economiser with its requisite by-pass flue. This chamber leads into the main chimney shaft, which is 150ft. in height from the floor level, and is provided with a circular gallery around its base, into which this chamber leads, and between which gallery and the main shaft are a number of small openings, the whole being so arranged that the products of combustion have to swirl round the gallery to enter the shaft—a provision to ensure the final depositing of any fine dust carried by the gases through the depositing-chamber. The chimney shaft is lined right to the top with firebrick, and a ventilated air space left between the firebrick lining and the main structure of the shaft, to avoid the outer walls being appreciably heated. In the London district this is quite desirable, since the rules of the County Council provide for such thickness of walls in the chimney shaft that the unequal expansion and contraction of these walls would be such as to lead to the disintegration of the brickwork, the inner skin coming into contact with gases possibly at a temperature of upwards of 2,000deg. F. As before mentioned, each boiler has its proper complement of firegrate, firedoors, etc., which are provided for the express purpose of enabling the boilers to be fired by coal alternatively or simultaneously with the absorption of heat from the waste gases of the destructor cells passing through the boilers. This arrangement fulfils a twofold object. First, the provision of the secondary fire before referred to, which is in the most desirable position for further heating the destructor gases immediately they enter under the boiler, should that operation be requisite, and having the further advantage that the heat so produced is ultimately completely absorbed by the boiler and thus turned into profitable use; secondly, to add to the steam-raising power of the boilers when the heat of the destructor gases is not sufficient to produce all the steam required, or, when the destructor cells attached to a particular boiler are out of order, to enable the boiler to be entirely fired by coal or coke.

Each of the destructor cells and the boiler furnaces is fitted with two systems of forced draught, one being an air blast, the other an induced blast produced by steam jets. The air blast is produced by three sets of fans coupled to and driven by electric motors, two out of the three fans being sufficient to supply 16,000 cubic feet of air per minute, the maximum quantity that could possibly be required, and to produce it at a pressure up to 3in. water gauge. The steam blast is derived direct from the boilers, and is arranged as a continuous system, so that

Digitized by Google

cells adjoining a boiler not in use can still obtain their steam blast from the other boilers in use. So much divergence of opinion still exists as to the relative merits of the fan blast and induced steam blast, that the Vestry, acting under my advice, settled to instal both systems, when they will be able to use either or both in combination as may be found most desirable in practice.

Ten out of the 12 dust-destructor cells are capable of burning with ease the 20,000 tons of ashbin refuse per annum which have to be dealt with by the Vestry. The charging of the cells with the refuse is to be effected in a manner which, though not novel, will perhaps be more effective than heretofore. The space available for the construction of an inclined roadway involved the use of a gradient of 1 in 15, not an unusual gradient for such purposes, but at the same time decidedly detrimental to the longevity of the horses drawing the carts, and it was



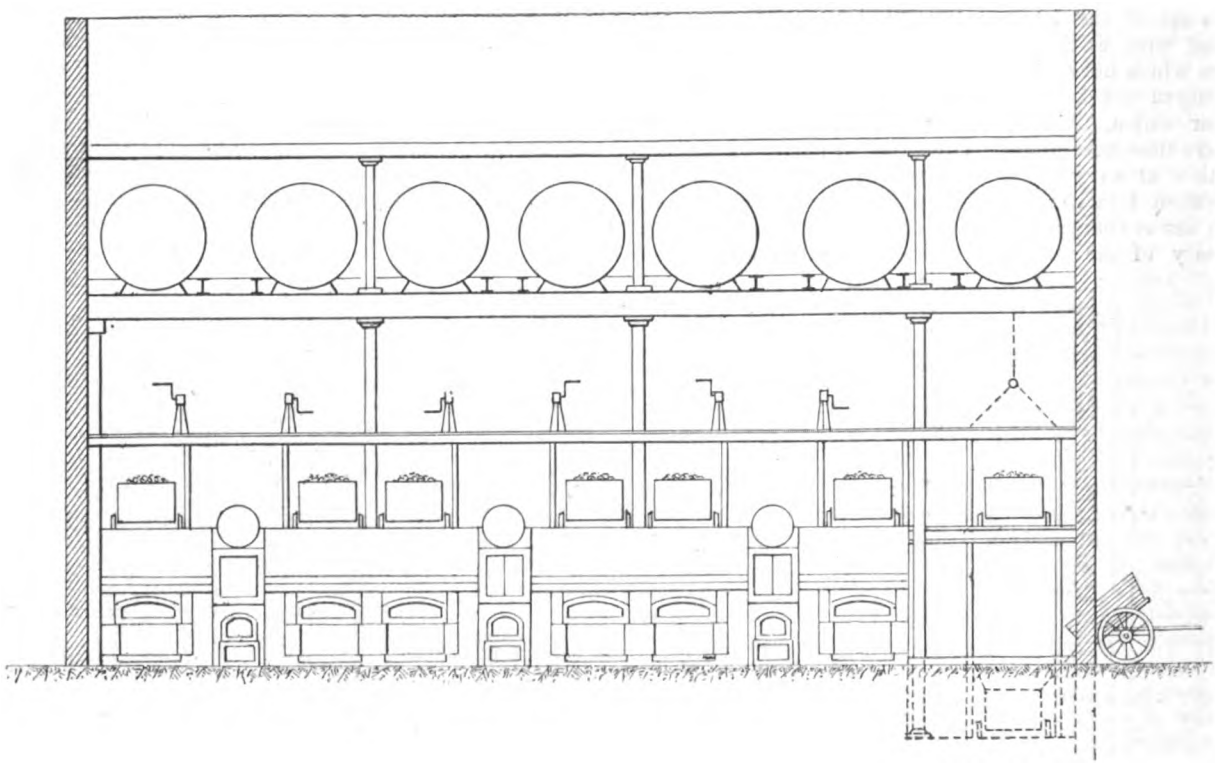
General Plan.

therefore decided to replace the elevated roadway with two electric lifts. Either of these lifts is capable of lifting a full load of, say, three tons of refuse, and, being in duplicate, no hindrance can happen to the delivery of refuse should one of them be put out of order. The refuse is tipped from the carts into a tipping wagon, sinking below ground level and raised by the lifts afterwards to a floor considerably above the level of the tops of the dust destructor and furnaces. These tipping wagons are then hauled by mechanical means into any desired position along the range of furnaces, and the refuse tipped from them into storage bins reaching from this floor to the level of the tops of the destructor furnaces. From these storage bins the refuse is discharged as required into charging trucks made after Messrs. Bulnois and Brodie's patents. These charging trucks are divided into compartments so arranged that the charging truck being brought over a horizontal door in the top of and at the back of the destructor cell, doors in the bottom of the truck corresponding with each compartment may be opened simultaneously with the door at the top of the cell, and the exact charge of refuse dropped through into the cell. There it falls upon an inclined hearth at the back of the firegrate, whence it is raked down through the clinkering doors in front on to the firegrates themselves. This arrangement enables a great deal of manual labour to be dispensed with, the whole of the transference of the refuse to the particular destructor it is destined to feed being accomplished by means of electric motors, and the storage bins referred to have a capacity equal to 60 tons of refuse, which will enable the furnaces to be fed during the night-time, and also during the greater portion of the time that intervenes between Saturday afternoon and Monday morning. The storage bins being placed well above, and out of contact with the hot brickwork of the destructor cells, the stored refuse is preserved under the most favourable conditions.

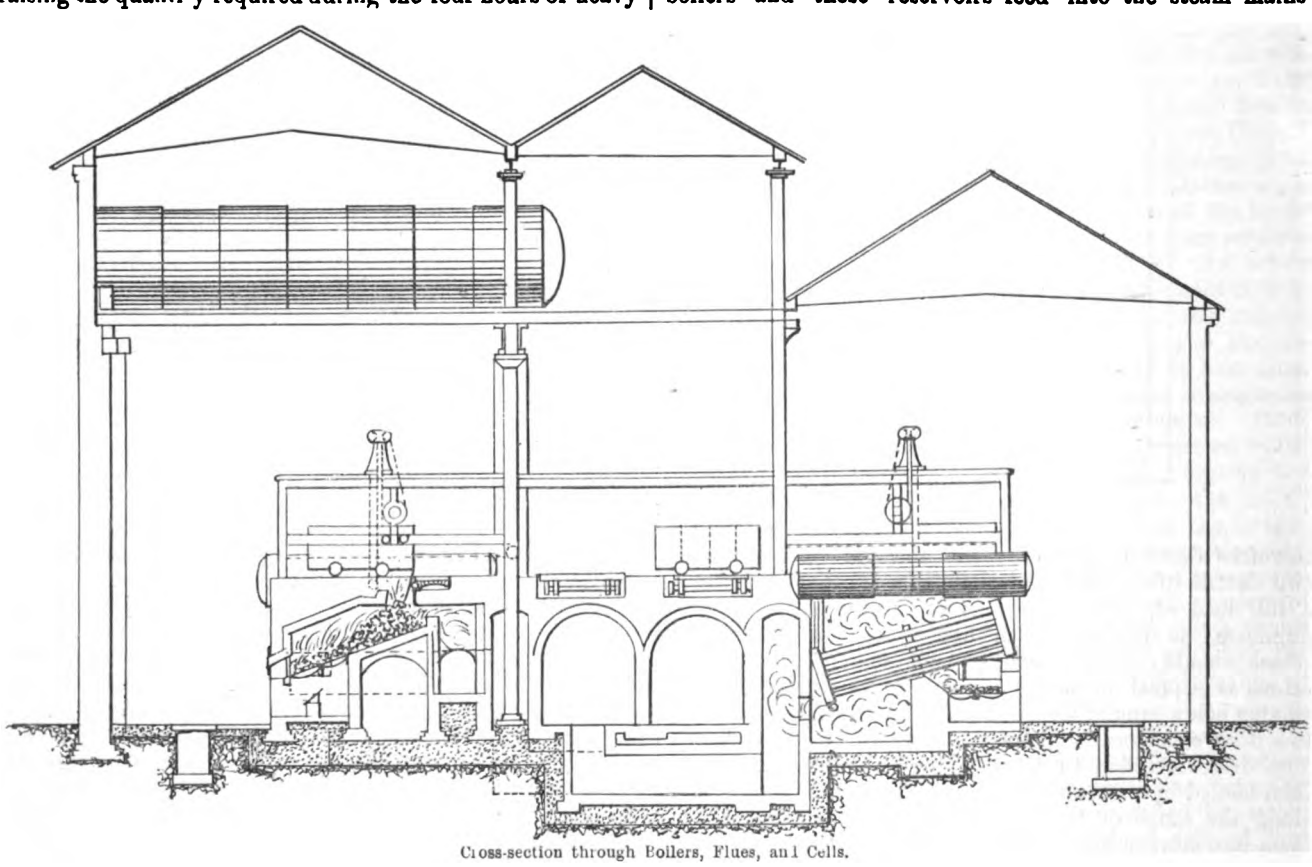
As mentioned previously, the principal object of the whole of this arrangement of boilers and cells is to get the maximum output of steam. I have calculated that the electric light station will require steam at 120lb. pressure at the rate of 12,000lb. per hour for four hours a day, 6,000lb. per hour for three hours a day, and 2,000lb. per hour for the balance of the 24 hours, or in all 100,000lb. weight of steam for 24 hours, and the contractors who tendered for the carrying out of the works were invited to state what proportion of this weight of steam they would guarantee should be raised by the consumption of ashbin refuse only. Many of them, including Messrs. Manlove, Alliott, and Co., undertook that no coal should be required to raise the requisite amount of steam daily. It must be borne in mind that the difficulty to be met in the combination of a dust destructor with an electric lighting station, from a

Digitized by Google

steam-raising point of view, is that whilst the refuse is being burned at an approximately even rate during the whole day, the steam for the electric light station unfortunately is required in very varying quantities, varying from a very small quantity during the greater portion of the day to a maximum, six or seven times the minimum, during the four hours of heavy load; and whilst the furnaces might be quite capable of raising the total quantity of steam required at an even rate, they might be incapable of raising the quantity required during the four hours of heavy load. To meet this difficulty, Messrs. Manlove, Alliott, and Co. propose to instal in conjunction with the boilers the patented thermal storage system of Mr. Druitt Halpin, and the arrangement of thermal storage reservoirs proposed for Shoreditch is shown on the accompanying sketches. Seven reservoirs, each 35ft. in length and 8ft. in diameter, are provided and connected up to the boilers, thereby accumulating the energy. The temperature in the reservoirs is never allowed to drop below the equivalent of 120lb. steam pressure to the square inch, but during the accumulation of the energy developed by the boilers the temperature is raised in both the boilers and these reservoirs until a temperature equal to a pressure of 200lb. per square inch is attained. When in each day the time of heavy load is attained at the central station, both the boilers and these reservoirs feed into the steam mains supplying the engines, and as the energy taken by the engines considerably exceeds that which the boilers are capable of generating, the pressure in both boilers and reservoirs gradually falls until the minimum of 120lb. is again reached, and the energy represented by this difference in temperature is that which has been taken up from the



Sectional Elevation along Front of Cells



Cross-section through Boilers, Flues, and Cells.

Digitized by Google

boilers during the day time by the thermal storage reservoirs. Thus is the energy, that would otherwise be wasted, accumulated and carried on to the time when it can be utilised by the electric light engines. An additional and not unimportant advantage accrues from the use of these thermal storage reservoirs, inasmuch as the feed-water is pumped into the reservoirs and not into the boilers, and hot water at the actual boiler pressure is allowed to gravitate from the reservoirs into the boilers to make up for the evaporation in the boilers. At the minimum temperature at which the storage reservoirs are standing, practically all the inorganic salts held in solution in the water are deposited in the reservoirs, and the boilers are fed with water free from these impurities. They therefore remain perfectly clean and unscaled on their water surfaces, and are always working at their highest efficiency, whilst the precipitate in the thermal storage reservoirs is in the shape of soft mud only, since the plates of the reservoirs are not exposed to the action of the fire, and they can be with perfect facility cleaned from this precipitated mud.

The combination of a thermal storage system with a set of dust destructors and boilers will, I believe, appeal to all of you as an ideal arrangement for the utilisation of the steam produced by the latter. You will notice that very high pressures are to be attained, 200lb. being the maximum. I have myself heard papers read before societies, in which it has been stated that higher pressures than 70lb. or 80lb. cannot be attained in boilers fired with destructor gases. Statements of this kind do not require much comment from me. It will be obvious to all of you that with destructor gases varying from 1,200deg. to 2,000deg. F., such a pressure as this, or, indeed, if it were desired, a much higher pressure of steam can be obtained. Perhaps those who have made such statements will be reassured when they find a firm of standing guaranteeing, under heavy penalties, the successful issue of a dust destructor thermal-storage scheme in which a pressure of 200lb. to the square inch has to be attained without the use of coal.

THE ELECTRIC LIGHTING OF BANGOR, WALES

The following report has been drawn up by Mr. F. H. Medhurst, the electrical engineer appointed by the Bangor City Council to assist them in the consideration of the question of introducing the electric light into Bangor.

In order to be in a position to supply electricity for public and private purposes from an electric power central station the Corporation must apply for a provisional order, or, if time presses, the local authority may make application to the Board of Trade for an electric lighting provisional license, which will have to be confirmed within seven years by a provisional order, granted by Parliament. As I understand that the gasworks are already taxed to practically their full capacity, I should recommend the Corporation to apply, in the first instance, and at the earliest possible date, for a provisional license, because it will not be possible to obtain a provisional order this year. Every provisional order or license must contain four schedules: The first, setting forth the area within which the order or license is intended to apply; the second, giving a list of streets in which distributing mains must be laid within two years of the date of the order or license; the third, giving a list of streets not repairable by the local authority; the fourth, stating the maximum price which it is proposed to charge for electric energy under the order or license. In this case the license, if applied for, would of course be applicable to the whole of the borough of Bangor, and I have marked on the accompanying plan the streets which I should suggest for the compulsory area, though it should be borne in mind that the Corporation will have the option of laying distributing mains in any other streets as well, and would, most likely, do so if the probable demand appeared to justify the necessary outlay. I have, however, based my estimates on an initial scheme to supply the compulsory area only. A Board of Trade unit (equal to $1\frac{1}{3}$ e.h.p. per hour) is the commercial unit of electrical energy; it is usually called simply "a unit," and will maintain a 10 c.p. incandescent electric light for $33\frac{1}{3}$ hours. I should recommend that 6d. be the maximum charge per unit to private consumers, and at this rate the cost of using a 10 c.p. incandescent light for an hour will be rather less than $\frac{1}{5}$d.

Taking into consideration the fact that the total length of streets embraced in the proposed compulsory area is about 5,500 yards, and that the principal shops, private houses, and public buildings of the town are included in the area, I am of opinion that I am well within the mark in counting on having 4,000 lights of 10 c.p. each in electrical connection with the mains within a year from the opening of the works. The mains are proportioned for the above number of lights, but as experience in other places has conclusively demonstrated that more than half of the lamps wired are never likely to be simultaneously alight, I have provided generating machinery at the proposed central station to supply rather over 2,000 lights of 10 c.p. alight at the same time, with, however, ample spare plant.

On the occasion of my visit to Bangor on June 5, I was most anxious to ascertain whether it would be possible to rely on water power, in whole or part, to supply the energy for driving the generating machinery. During the morning Dr. Grey Edwards and Mr. Smith Owen kindly conducted me to the Penrhyn Mills and to the Coetmor Mills. I am of opinion that a power station could not be of any practical utility for electricity supply purposes unless the stream were damned up, or some other method of water storage resorted to above the Coetmor Mills. But such storage would necessarily take place during the daytime—in fact, during the time when people would not be requiring to use artificial light. The daytime is, however, the time of greatest activity at the mills, and I was, therefore, forced to the conclusion that no scheme for utilising water power for lighting Bangor electrically could be carried out without serious interference with existing water rights. But even if this difficulty could be overcome, it would be necessary to erect steam plant, to be used only in case of severe frost or of exceptional drought, and I find that, taking everything into consideration, the possible saving in coal and wages would be more than swallowed up by the interest and sinking fund on the increased capital outlay that would be involved by having to erect water power, plus a complete stand-by steam plant, by the extra cost of mains, and by the cost of improving the water power.

During the afternoon of June 5, you, sir, and Dr. Grey Edwards were good enough to escort me on my tour of inspection, and amongst other things you showed me three sites that would probably, I believe, be available for the erection of electricity supply works. The sites were: (1) adjoining the gasworks; (2) on the seashore (used, now, I understand, as a refuse tip); (3) on the Euston-road. Site No. 1 appears to me to be the most convenient, and if the Corporation can obtain the land at a reasonable price I should recommend that the proposed works be erected on this site. It is fairly central, and water can be obtained without expense for condensing purposes—a fact which must produce an economy of about 25 per cent. in fuel. Site No. 2 is made-up ground, and its adoption might easily involve a heavy outlay for foundations for the chimney shaft. Site No. 3 has the advantage that a siding might easily be made from the railway line, and the effect would probably be to so reduce the cost of coal by the amount that would otherwise be paid for cartage, etc. But the siding cannot be made without expense, and the fact of condensing the water being available at the gasworks site more than compensates for the saving of about 1s. per ton for cartage.

The system I strongly recommend for Bangor is the high-tension alternating-current system, with transformers in sub-stations, and a low-tension network of mains for private supply. The current will be generated at a pressure of 2,500 volts at the generating station, and it will be conveyed by means of well-insulated stranded copper cables, drawn through cast-iron pipes with drawing-in boxes at intervals of about 100 yards to the various sub-stations marked on the plan. At these points transformers will tap the high-tension mains. The low-tension mains will likewise consist of well-insulated stranded copper cables, drawn into cast-iron pipes (but not the same pipes as those containing the high-tension cables), with junction-boxes at intervals of about 50 yards. The boilers will be two in number (one spare), and each will evaporate 2,500lb. of water per hour when working under normal conditions. It will, however, be possible to "press" them up to 3,500lb. of water per hour, if necessary, for short periods of time. The main engines will be three in number (one spare), will be vertical, compound, and condensing, and will work at about 260 revolutions per minute. The alternators will be coupled direct to the engines, and will be on the same bed-plate. There will be two exciting steam dynamos (one spare). In the event of the lighting scheme alone being carried out, I should propose to provide for the small amount of current that may be required during the daytime by employing an alternating-current motor dynamo coupled direct to a continuous-current dynamo and a small set of accumulators. During the night the steam alternators would be employed to charge the accumulators through the intervention of the motor dynamo, and during the daytime—in fact, for two shifts of eight hours each out of three—the accumulators would supply current to the continuous-current dynamo (which would then be used as a motor), and this would revolve the alternating-current motor (which would then be used as an alternator), thus giving a supply of alternating current to the mains. The practical effect of this arrangement is twofold: it enables the services of stokers to be dispensed with during times of light load—say, for 10 hours out of 24—and thus causes a considerable saving in labour; and, secondly, it tends to reduce the consumption of coal by enabling the steam-engines to work at

Digitized by Google

nearer full load than they would otherwise do. The capital expenditure for the scheme I have recommended and described will be, approximately, as follows: Two boilers, economiser, feed pumps, and steam and exhaust pipes, £1,800; surface condenser and circulating pumps, £350; three 30-kilowatt steam alternators and two steam exciters, £2,400; buildings and foundations, £2,000; switchboard, £500; day load plant, £450; travelling crane, £130; mains, laying and making good, £4,920; site, £200; unforeseen expenses and contingencies, £250—total, £13,000. Statistics prove that the average price to be expected per lamp of 10 c.p. per annum is about 10s. Therefore, the total revenue from 4,000 lamps will be £2,000. The Corporation can, I am informed, borrow 3¼ per cent., whilst 2¼ per cent. must annually be set aside to form a redemption fund for liquidation of the loan. We have then the following results—Revenue: 4,000 lights at 10s., £2,000. Working expenses: coal, £240; engineer, £150; wages, £400; oil, waste, and stores, £66; repairs and maintenance, £190; interest and redemption on £11,300, £719. Total, £1,792. From the above figures it will be seen that from the very commencement of the undertaking a fair net profit is likely to be made after payment even of interest and sinking fund. But it must be borne in mind that when the demand comes to exceed the 4,000 lights on which I have based my estimates—and those are well on the safe side—the future revenue will certainly increase in a much higher ratio than the expense. For example, the capital cost of a scheme for 6,000 lights would be about £16,000, but the probable net profit would be not less than £500 after payment of interest and sinking fund. There appears no reason why the demand should not equal 6,000 lights of 10 c.p. in three or four years' time. Then, again, the Corporation may rest assured that if it does not itself see its way to carrying out the electric lighting scheme, some outside company will very likely apply for and (unless the Corporation itself takes action) obtain a provisional order, and in that case the local authority would very possibly find itself in the position of having to pay a very large bonus in a few years' time for the privilege of purchasing rights which ought never to be forfeited.

I have most carefully considered this matter, and the suggestions I am about to make will, I trust, prove of interest to the Corporation. The capital expense of an electric tramway on the overhead trolley system from the Clock Tower to Garth Point will be equivalent to an addition of about £8,600 to the cost of the lighting installation. In arriving at this estimate I have taken into consideration the fact that the same boilers and engines and the same buildings (with some addition for an accumulator battery) will be used for both lighting and traction purposes, and the extent to which the schemes have been combined will be most readily appreciated when I state that the cost of the tramway scheme alone would, if carried out in the best manner, not be less than £12,000. I propose a single track only, with, however, a loop or siding half-way between the termini, so that the cars may pass one another halfway. I would suggest that each main engine at the generating station be coupled direct to a 30-kilowatt continuous-current dynamo, as well as to its alternator, the engine being placed between the alternator and the dynamo. I suggest also having a set of 255 accumulators; the tramway will derive all its energy from this battery. The engines at the generating station will charge the batteries—which will also be at the central station—during the hours when the tramway is not working, and as the charging current will always be equal in amount to the difference between the full output of the engines and the current required for lighting purposes, it follows that during the whole period of charging the engines will be working at full load, whilst for one shift out of three the engines will be at rest, and the stoker may be sent away. The importance of working the engines at practically full load almost all the time during which they will be running may best be judged from the fact that whereas on trial it is quite possible to get a unit of electrical energy from about 2lb. of coal, yet the average consumption of coal at electricity supply works cannot be far short of from 8lb. to 15lb. per unit sold. By combining the electric light and the electric tramway scheme, the standing charges will not be very materially increased, whilst each undertaking will naturally be debited with its fair proportion, so that, after very careful calculation, I have come to the conclusion that the working expenses of the electric lighting department will be reduced by about £210 if the electric tramway be put down and the two concerns be worked together. I also believe that the electric tramway could not possibly fail to bring increased custom, and hence increased profits, to the pier now in course of construction. I assume that the charge be 2d. per journey from the Clock Tower to the pier, and *vice versâ*. It may also be assumed that the two cars (and I do not propose that more than two cars shall be in use at the same time) start from their respective termini at the same time, pass one another half way, and make five journeys per hour each, including stoppages. The cars will be constructed so as to carry 32 passengers each, and I do not think it extravagant to assume an average load of four passengers per journey per car. Then each car would therefore earn 8d. per journey, or 3s. 4d. per hour. The two cars would therefore earn 6s. 8d. per hour between them. Now, the cars would be at work for 12 hours per day, so that the gross earnings would be £4 per day. The cars would probably not run during church hours on Sunday, so that the gross revenue may fairly be taken at £4 a day for 313 days, and £2 per day for 52 days. Therefore the gross revenue works out at £1,356. Now, the total working expenses should certainly not exceed 5d. per car mile, or £626 in all. This would leave a profit of £730. The capital required has already been stated at £8,600. Interest and sinking fund, calculated as in the electric lighting scheme, amounted together to £473, leaving a net profit of £257. But to this sum should be added any saving in the working expenses of electric lighting scheme, as well as an increase of revenue to the new pier. The former I have already estimated at £210 per annum, and I think that £150 is a very cautious allowance to make for the increase of revenue which the pier is almost certain to derive from this convenient and cheap mode of access. The total net advantage, then, which is in my opinion most likely to accrue from the direct and indirect operation of the electric light is certainly not less than £817—and this after payment of all interest and all other capital charges, and after making allowance for maintenance and depreciation.

I think the only conclusions to be drawn from the above considerations are: (1) That electric lighting works have every prospect of proving a useful and profitable undertaking at Bangor, and that if they be carried out quite alone they would most likely prove a source of considerable alleviation to the rates in from two to five years' time; (2) that an electric tramway, in combination with the electric lighting works, will not only earn a fair profit, but must tend to increase the revenue of the pier, and decrease the working expenses of the electric lighting undertaking; (3) that the advantages of the combined scheme are great indirectly, and that directly there is almost certain to be a net profit of over £800, if the combined scheme be carried out; (4) that as the capacity of the gasworks is already taxed to the utmost, no time should be lost in passing the necessary resolutions to carry out the electric lighting scheme, and that for economical reasons the electric tramway should be carried out at the same time, the total capital expenditure of the combined scheme being about £22,000. Finally, I can only say that if, notwithstanding the fact that I have used my utmost endeavours to express clearly and logically my reasoning and my conclusions, there still remain any details upon which the committee would wish to have additional information, I shall be very happy to keep any appointment that may be suggested, and to explain fully anything that possibly may not have been thoroughly elucidated.

The proceedings of the Council in connection with this matter appear in our "Business Notes."

LEGAL INTELLIGENCE.

THE BRITISH INSULATED WIRE COMPANY, LIMITED, v. PRESCOT URBAN DISTRICT COUNCIL.

This case came up again last week in the Court of Appeal before the Master of the Rolls, Lord Justice Kay, and Lord Justice A. L. Smith.

It was an appeal by the plaintiffs from the judgment of the Divisional Court (Mr. Baron Pollock and Mr. Justice Wright) on a special case stated in an action. On November 18, 1892, an agreement was entered into between the plaintiffs and the defendants whereby the plaintiffs agreed to light with electricity the streets of the defendants' district for a period of five years from January 1, 1893. The agreement provided for the reference of all disputes thereunder to arbitration. The agreement was sealed, but it contained no penalty clause. The plaintiffs carried out the agreement by supplying electric light from January 1, 1893, to March 31, 1895, and were paid the sums due to the end of the quarter ending June 30, 1894. This action was brought to recover £278. 9d. 9d. for the supply from July 1, 1894, to March 31, 1895. The question for the opinion of the Court was whether the agreement was binding on the defendants by reason of its not specifying a penalty to be paid in case its terms were not carried out. By Section 174, Sub-section 2, of the Public Health Act, 1875, "every such contract" (contract made by an urban authority) "shall specify the work, materials, matters, or things to be furnished, had, or done, the price to be paid, and the time or times within which the contract is to be performed, and shall specify some pecuniary penalty to be paid in case the terms of the contract are not duly performed." The Divisional Court held that the provisions of the sub-section were imperative, and that therefore the contract was void, and gave judgment for the defendants. The plaintiffs appealed.

Mr. J. Lawson Walton, Q.C., and Mr. L Sanderson appeared for the plaintiffs; Mr. Danckwerts appeared for the defendants.

During the course of the argument it was stated that the defendants were willing to make the payments, but that the district auditor and the Local Government Board had refused to sanction them. Thereupon,

The **Master of the Rolls** said that it was just and right that these arrears should be paid, and that if this opinion were intimated to the proper authority, the Local Government Board would

Digitized by Google

doubtless allow the arrears to be paid, and that a new contract should be entered into containing a penalty clause.

The case was accordingly adjourned, to enable the parties to go before the Local Government Board. Finally, upon the case being called on, it was stated that the Local Government Board would sanction the payment of the arrears, and it was arranged that a new contract should be entered into in substitution for the present one, its terms to be settled, in case of disagreement, by some third party. Upon these terms the appeal was dismissed.—*The Times.*

A DISPUTED CONTRACT.

At the Liverpool Assizes, before Mr. Justice Wills, without a jury, the case of Ball *v.* Ellison and Son has been heard. This was an action to recover money for a lightning conductor. The plaintiff, Joseph Ball, of Oldham, was represented by Mr. Pickford, Q.C., and Mr. Horridge, and the defendants, who are architects in Liverpool, by Mr. Taylor, Q.C., and Mr. A. Rutherford.

The case for plaintiff was that in the summer of 1893 he entered into a contract with the defendant firm to fix a lightning conductor to the chimney of a hospital which the Toxteth Guardians were erecting. The defendants were the architects in the matter. After the contract had been made it was alleged that the character of the chimney was altered, and stouter and longer rods had to be used. Before doing the work plaintiff informed the defendants of the extra requirements, and no objection was made. The work was completed, and there were no expressions of dissatisfaction with it. Ultimately plaintiff sent in his bill for £163. 19s. 6d. to the defendant firm, but it had not been paid.

The defendants, without admitting liability, had paid into Court £57. 10s.

A number of witnesses were called in support of the case for the plaintiff.

The defence was that on the contract the defendants had not made themselves personally liable, but had simply acted for the Toxteth Guardians, who had reaped the benefit of the work. Furthermore, Colonel Ellison, of the defendant firm, expressed dissatisfaction at the way the work was done, and on that ground, and on the ground of excessive cost, he refused to grant plaintiff a certificate for payment.

His **Lordship** decided that the contract was made with the defendants, and gave judgment for the plaintiff for £140 and costs, which included the amount paid into Court.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.

Mr. Justice Chitty was asked on Saturday to sanction an alteration in the memorandum of association of the Consolidated Telephone Construction and Maintenance Company, Limited. Incorporated in 1881, the Company had a nominal capital of £300,000, divided into 300,000 £1 shares. Various alterations had been made from time to time, and the present nominal capital was £234,938, divided into 47,363 6 per cent. preference shares of £1 each, and 224,850 ordinary shares of 10s. each, and 75,150 ordinary shares of £1 each. All the ordinary 10s. shares had been issued and were fully paid up. The memorandum of association expressed the objects of the Company in very wide terms, but there was now a prospect of profitable trading in matters which were not considered to be covered by the memorandum, and it was proposed to alter the latter so as to give the Company power "to manufacture, buy, sell, and deal in articles, apparatus, and inventions in connection with electricity or to which electric power may be applied, and to manufacture and deal in mechanical apparatus and inventions whether connected with electricity or not," and to alter the title of the Company to "The Consolidated Telephone Construction and Manufacturing Company, Limited." The petition stated that owing to the expiration of patents belonging to the Company other manufacturers were enabled to manufacture telephones in competition with the Company, and there was a large importation of telephonic apparatus from abroad. From these causes the manufacture of telephones and telephonic apparatus had become less lucrative than it formerly was, and the plant and appliances of the Company were only partially employed. It was therefore proposed to go in for the manufacture of scientific and mechanical instruments of all kinds, from which considerable profits were anticipated.

His **Lordship** gave the necessary sanction.

COMPANIES' MEETINGS AND REPORTS.

CROMPTON AND CO., LIMITED.

The annual general meeting of the above Company was held at Cannon-street Hotel on Friday last, Viscount Emlyn occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, which we printed in our last issue, said that in connection with the reduction in profits there was a satisfactory feature, which was that although there had been a considerable reduction in prices, the falling off in profits was due mainly to the lack of orders in the first six months of the business year. Business had then been so slack that no profit was made, and the whole of the £7,000 profit had been practically earned in the latter half of the year, when the order-book was well filled and the works were very busy. New contracts showed better prices, and business generally was improving. Several changes had been made with a view to greater economy, and in connection with these the accountant's department had been removed to London, and better departmental control had been established. The Court of Chancery had sanctioned the reduction of capital. The directors had hoped that the issue of debentures last January would be fully subscribed, but £82,000 only had been taken up. The item of stock had been slightly reduced, as had investments in subsidiary companies, by writing off. Part of the reduction in profits was due to the purchase of small machine tools, not covered by the depreciation account. There had also been a small loss due to the misreading of a specification. At the last meeting they had anticipated that the electric cooking branch would prove important, and this had turned out to be the case. They had got £1,000 from a French firm for the French rights, in addition to royalties, and they had concluded licenses for Switzerland and Austria-Hungary. It had been decided to close the works at Little-road, in order to concentrate the the business at Chelmsford. Last year the orders from Sydney had appeared satisfactory, but it had since been discovered that the contracts which had been made were unsatisfactory, for the payments were to be made by instalments The Australian company had come to grief, and the realisation of assets might take some time, but it was hoped that the debenture-holders (who included this Company) and the secured creditors would be paid. It had been considered advisable for Mr. Albright to start for Australia that night, with the view to looking after contracts there. The arc lamp department continued to show excellent results. The Company would continue to have the services of Mr. Crompton and Mr. Albright as managing directors. He believed that the future of the Company promised considerable improvement.

Mr. R. E. Crompton, in seconding the motion, said that there had been enough of prophesying, and all he would say was that they would do their level best to get things round. An improvement had sprung up six months ago.

Mr. Evans thought that more should be written off various items of the assets.

Mr. Kitchen considered the sum under trade debtors to be enormous, and had been told that the Company were the worst firm in London for cutting prices. He was of opinion that they were overtrading at low prices.

Mr. Crompton said that it was very difficult for any firm to get profitable contracts unless they took financial risks, and in all ordinary cases the profit was very small indeed.

Viscount Emlyn stated that 10 per cent. was written off the patents account every year. The goodwill was put down at a very fair figure. The £1,000 received from the French Company would come into next year's accounts. They were obliged to keep down prices, or they would have no business at all.

The motion having been adopted, Mr. Bernard Gibson was re-elected a director, and Messrs. J. H. Duncan and Co. were reappointed auditors.

Viscount Emlyn stated that having been elected chairman of the Great Western Railway Company, he found he had so much work on his hands that he would have to resign the chairmanship of the Company.

MANCHESTER EDISON-SWAN COMPANY, LIMITED.

The thirteenth ordinary general meeting of this Company was held on Thursday last at the Company's works, Broadheath, Mr. V. K. Armitage, the chairman, presiding.

The report and balance-sheet for the year ending May 31 showed that the net profit, including last year's balance, amounted to £1,590, which it was proposed to appropriate as follows: To payment of dividend at 5 per cent. per annum, £1,303; balance to be carried forward, £287.

The **Chairman**, in moving the adoption of the report and balance sheet, said that the document was one which they submitted with a considerable amount of satisfaction. Although the last 12 months had been a period of very great trade depression, as the shareholders were aware, the Company were still able to return to what prior to last year was their ordinary course, and to recommend a 5 per cent. dividend, which he considered a very satisfactory state of affairs. Their gross profits had been £5,877, as against £5,200 in the previous year, and the net profit £1,590, as against £1,334 last year. In addition to that they had taken off as depreciation £591, as against £226 last year, so that they showed a trade improvement of £614 over the trade of 1894. The directors attributed that almost entirely to the additional work they had got in the Altrincham lighting station, which the shareholders had just had an opportunity of looking through. The directors had no doubt that in the future they would find a very great advantage from their connection with the Altrincham and Bowdon Company, and from the increased facilities they had in their Broadheath manufacturing works. Since the end of May last they had obtained additional orders to the amount of £73,000, which he considered very satisfactory.

Mr. W. P. J. Fawcus, the managing director, seconded the motion, and gave details as to the increasing work which was being done by the Company.

The resolution was passed.

The **Chairman** moved a resolution declaring a dividend of 5 per cent., the surplus of the profit to be carried forward.

Mr. F. B. Ross seconded the motion, which was adopted.

Mr. V. K. Armitage, the retiring director, was re-elected, and the auditors, Messrs. Jones, Crewdson, and Youatt, were also reappointed.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The half-yearly meeting of the shareholders of this Company was held on Tuesday in Liverpool, Sir W. B. Forwood, chairman of the board of directors, presiding.

Sir W. B. Forwood, in moving the adoption of the report and statements of accounts for the half-year ending June 30 said they were of a satisfactory and encouraging nature. Their traffic for the first six months had always in their experience been considerably less than that of the second half-year. The reason was this: in the first half-year they had to depend almost entirely upon what he might call business traffic alone, except during the period of Whit week when they had some additional holiday traffic. In the second half-year they got most part of their holiday and excursion traffic. Therefore they compared their figures with those for the corresponding period of last year. They would notice that their number of passengers had increased from 2,861 437 to 3 460,060 in the past half year. Looking at these figures a little more in detail, he thought they would find that there had been a very satisfactory increase in the number of first-class passengers. The number had increased from 277,653 to 400,260 and there had also been a very satisfactory increase in the number of second-class passengers The number had gone up from 1,246,975 to 2 114,462 Their gross receipts amounted to £28,082, against £20 011 in the corresponding half of last year, showing an increase of £8,071. The gross expenditure had been £18,658, as against £14.947, or an increase of £3,711; that was to say, they had earned an increased revenue of £8,071, of which they had spent in earning it £3,711, but part of that expense had gone in the increased mileage. The increase in the running was 46,000 miles, and they had worked 16 stations instead of 14, consequently, they had had the additional expense of two stations. He was glad to say their traffic had continued to progress since those accounts were made up. During the six weeks which had elapsed since June 30 they had increased their traffic by 55,000 passengers, and had taken £1,568 more money than they did during the corresponding six weeks of last year. The net available profit for dividend was £8,076, and they proposed to declare a 5 per cent. dividend upon their preference capital, and also a dividend at the rate of 2¼ per cent. on the ordinary shares, leaving a balance of £1,302 to be carried forward to the next half-year. Looking at the accounts a little more in detail, he found that their receipts for passengers had averaged 1 92d. per passenger, as against 1 65d. This increase, which meant nearly one third of a penny per passenger, was due to the advance they had made in the workmen's tickets and to the increased first class traffic upon the line. The ratio of expenditure to their revenue had been 66 43 per cent., as compared with 74 69 for same half of last year. The ratio of the cost of their locomotive expenditure to net revenue was 24 26d., as against 21·28d. That was an increase of nearly 3d. This was due to their having had more repairs to effect to their motors than they had at the similar period last year, the long frosty winter being particularly trying to their motors. The proportion of their travelling expenses to their revenue was 37·54d., as against 41·99. That was also a satisfactory feature, as showing that in proportion to their revenue their expenses had gone down. Their revenue per train mile had increased from 18·10d. to 21·65d.—that was to say, they had increased their revenue per train mile 3·55d. per cent. The expenditure per train mile had gone up from 2 88 to 3·49, an increase of 0 61d. While their revenue had increased 3·55d., their expenses had increased only 0·61 per train mile. In reference to the physical condition of their structure, it had never been in a better condition than it was at this moment. With respect to the Southern extension, that was to say, the extension from the Herculaneum Dock, the present terminus, to a point in Park-road near the Dingle, they had let the contract at a figure within the estimate made by their engineers, and he might say that the contractors were already very busy at work. The directors had every reason to anticipate that this new extension would be completed within the time stated in the contract—namely, 12 months.

Mr. James Barrow seconded the motion, which was agreed to without discussion.

The **Chairman** next moved that a dividend be declared of 5 per cent. per annum on the preference shares, absorbing £2,529. 0s. 9d, and of 2¼ per cent. on the ordinary shares, amounting to £4 244 17s. 9d., and that the balance of £1,302. 18s. 11d. be carried forward to next half-year's account.

This was also seconded by **Mr. Barrow**, and carried.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY, LIMITED.

The half-yearly meeting of this Company has been held at Bristol, Mr W. Butler occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, said that during the last six months they had had much anxious work in connection with the construction of the electric line to Kingswood. The permanent way was finished, and the overhead construction was nearly completed. The power station was in an advanced state; the boilers and two of the three engines were in place, whilst the dynamos were also fixed. The trucks and motors were all in the station being fitted together, and the car bodies were practically completely and would be delivered in about a fortnight. The directors anticipated that a very few weeks will see everything ready for work. He believed that they would have one of the most complete electrical installations ever constructed.

The motion was adopted.

IMPERIAL TRAMWAYS COMPANY, LIMITED.

The report of the directors to June 30 last states that compared with the first half-year of 1894 the gross receipts of the Corris Railway show a slight falling off in the goods department, consequent upon the enforced idleness of some of the slate quarries during the exceptionally dry season. The expenses are approximately the same, and the net profit enables a dividend of 5 per cent. per annum to be paid, after meeting the interest on the Company's debenture stock. The working of the Dublin Southern District tramways during the past six months will not be expected to afford any proper comparison with the corresponding period of previous years, inasmuch as the traffic has been seriously disorganised by the electrical reconstruction works in progress. It will be observed that the net deficiency on the working of the undertaking amounts to £395, and has been charged against the Imperial Company's reserve fund. The permanent way reconstruction and electrical equipment of the lines between Dublin and Kingstown are well advanced, and traffic on the Dalkey section will shortly be discontinued to allow of that also being taken in hand. The receipts from the Middlesbrough tramways again show a satisfactory improvement, whilst the expenses of that department compare favourably. The working of the river steamers, however, has proved somewhat disappointing, the receipts exhibiting a small decrease and the outlay having been rendered greater than usual in consequence of extensive repairs. The gross receipts of the Reading Tramways have been well maintained, and compare very closely with those of the corresponding half-year. On the other hand, the expenditure has been £135 less, so that there remains an available balance of £809, sufficient to allow of a dividend of 6¾ per cent. per annum, as against 5½ per cent. in the same period of 1894. The receipts from the several undertakings give a gross revenue of £1,268, reduced by the usual expenses to £1,229. To this amount has to be added the balance brought forward from last account of £719, making £1,949 for disposal. Interest already paid upon the Company's 4½ per cent. debentures has absorbed £458, and the directors propose that the remaining sum shall be appropriated in the payment of the dividend on the 6 per cent. preference shares, for dividend at the rate of 1½ per cent. per annum on the ordinary capital, and to carry forward £341.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

The report of this Company for the past half-year states that the reduction of the nominal amount of the ordinary capital of the Company from £10 to £5 per share authorised by the shareholders has been sanctioned by the court. The working profit for the past year amounts to £55,924. 0s. 11d., against £52,804. 8s. 11d. for the year ended June 30, 1894, or an increase of £3,119. 12s. The deductions from the working profits of the year have been very heavy, and the amount available for reserve and dividend amounts to £21,491. 19s. 9d. The directors recommend a dividend of 3 per cent. upon the ordinary shares. The report adds: "The working account shows that the earnings of the steam trams amounted to £83,699, on 1,273,342 miles run, and 15,841,584 passengers carried. The expenses were £48,348, or 9s. 11d. per mile, and the net profit of the section £35,351. The horse department earned £27,888, of which £22,056 was taken by the omnibuses. The 'buses ran 552,164 miles, and carried 2,973,983 fares; and the horse cars ran 152,895 miles, carried 1,320,344 passengers, and earned £5,165. The outgoings of the department were £25,494, or 8 67d. per mile run, and the profit £2,394. The cable section earned £36,744, ran 743,805 miles, and carried 6,842,538 passengers. The working expenses were £16,830, considerably less than half the receipts, and equal to 5·43d. per mile, against 8 67d. in the horse section, and 9·11d. for steam. The electric section shows up worst. The traffic, etc., receipts on 138,925 miles run and 1,154,345 passengers carried, were £9,093, and the expenses £10,828, equal to 18·43d. per mile, entailing a deficit on the section of £1,735. Deducting this amount from the profits earned by the other sections, the net balance of earnings comes out at £55,924,"

BELFAST STREET TRAMWAYS COMPANY.

The forty-sixth ordinary half-yearly meeting of this Company was held on Tuesday in Belfast, Mr. W. M. Murphy being in the chair.

The **Chairman**, in moving the adoption of the report and accounts, said that in connection with the matter of meeting public requirements the question cropped up of mechanical traction. This was creating great attention now both in the United Kingdom and abroad. In the United Kingdom, owing to the conditions under which the tramway concessions were held, this question was rather behind what it was in the rest of the world. In the United States, out of a total of some 14,000 miles of street tramways, there were over 10,000 worked by electricity. In the Continent of Europe, and especially in Germany, through which he travelled last year, electricity was fast taking the place of horse-power, and he believed in 20 years the horse tramway would be a curiosity. Something had been said about the danger of mechanical tramways, but he might mention a fact in this connection which came under his notice in the last few months. The Dublin Tramways Company were promoting a Bill in Parliament to enable them to work their system by electricity instead of horse-power, and one of the questions raised in the House of Commons was the alleged danger of electrical lines to the public. They had the evidence of the engineer of the Walsall Company, whose lines had been worked

Digitized by Google

by electricity, and that gentleman told them that the company had insured itself against accidents to persons, and that the insurance company were in favour of the electrical system. One ounce of fact like that was worth a ton of theory, and it proved that electrical tramways were not more dangerous to the public than horse-power. In point of convenience, also, electrical cars had the advantage. The Belfast Street Tramways Company only having a lease of the lines for 12 years, it would be utterly impossible for them to attempt the large expenditure which would be necessarily incurred in adopting the electrical system. They had expressed, however, to the Lord Mayor and town clerk their willingness at any time the public demanded the change, to take it into consideration and discuss the matter with the Corporation. The Corporation at present did not think it desirable to move in the matter, but as far as the Company were concerned they were open at any time to receive suggestions or proposals on the subject if the feeling of the public was in favour of this system of traction. The people of this country did not know much of it, but as soon as they had experienced the benefits of an electrical system he believed they would demand it.

Mr. Fry seconded the motion, which was carried.

Mr. R. Johnston (shareholder) enquired which of the two systems—horse and electricity—was the cheapest to work, and the

Chairman, in reply, said experience had shown that the electrical system was cheaper than horse-power. Mechanical traction produced improved speed, and the receipts were thereby enormously increased.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Genoa.—The Royal Arsenal Authorities in Genoa invite tenders by August 21 for the supply of 6,800 kilogrammes of half-round copper wire. Estimate, 11,900 lires. Security, 1,190 lires.

Torrevieja.—Tenders are invited by August 20 by the municipal authorities of Torrevieja, Alicante, Spain, for the concession of the electric lighting of the town. The annual rental named is 4,000 pesetas for 100 16-c.p. incandescent and three 400-c.p. arc lamps.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895, for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Selby.—The Selby Urban District Council are prepared to receive tenders for the erection of three lightning conductors for the water tower and engine chimney at the waterworks, Selby. Full particulars can be obtained from Mr. W. Curry, surveyor, Town Hall, Selby. Tenders must be received not later than the 19th inst., endorsed "Lightning Conductors."

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f. This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas. Provisional security 10,000f.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep burning at the same time 2,200 8 c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Killarney.—The Commissioners for the Control of Lunatic Asylums, Custom House, Dublin, invite tenders for the electric wiring of the Killarney District Lunatic Asylum, the same to be connected to the supply mains (high tension) of the Killarney Electric Lighting Company. Forms of tender will be issued on application to the above Commissioners on deposit of £1, which will be returned to all persons who have sent in *bonâ fide* tenders on return of specification. The plans and specification can be seen at the asylum or at the office of the engineer, W. Leake, Esq., 30, Victoria-buildings, Manchester. Tenders are to be sent in by 30th inst.

Sunderland.—The Corporation invite tenders for (*a*) high-tension and low-tension concentric cables; (*b*) cast-iron pipes and box frames and covers; (*c*) stoneware casing, boxes, and bell-mouth protectors; (*d*) high tension transformers for alternating current; (*e*) meters for alternating current. Specification, etc., can be obtained on payment of one guinea at the office of the borough electrical engineer, Electric Supply Station, Sunderland. The deposit will be refunded on receipt of the specification and conditions of contract with a *bonâ fide* tender. Tenders should be delivered at the town clerk's office by Monday, 26th inst.

Portsmouth.—Tenders are invited for wiring and lighting by electricity the police stations at Buckland, Southsea, Portsmouth, and Portsea Full particulars can be obtained, and specifications can be seen, at the Town Hall, where a form of tender can also be obtained. Form of tender supplied to be completely filled in and sent under cover to Mr. Alexander Hellard, town clerk, by 3 p m. on 27th inst. Form of tender must include a declaration that the person making the tender pays not less than the trade union rate of wages, and observes the hours of labour and conditions recognised and in practice obtained by the trade unionists in the borough.

Islington—The Vestry are open to receive tenders for the wiring of the Vestry Hall and municipal offices in Upper street, N., and for the supply of fittings. Specification, etc, can be obtained on application to the electrical engineer, Electricity Department, 50, Eden-grove, Holloway, N. Deposit of £1. 1s. will be required for the forms, but such deposit will be returned on receipt of a *bonâ fide* tender. The contractor whose tender is accepted will be required to pay his employés engaged on the work the trades' union rate of wages and observe trades' union conditions and hours of labour. He will also be required to enter into a contract and to find two sureties for the due execution of the work. Tenders must be sent in by 27th inst

Wakefield.—The Corporation invite tenders for the supply and erection of the following: Section A—boiler-house plant (boilers and fittings, mechanical stokers and engine economiser, feed-pump, injector, etc.); Section B—engine-house plant (steam alternators condensers, oil filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tank, etc.); Section C—main switchboard and instruments; Section D—underground work (cables, junction-boxes, culverts, and trenching, etc.); Section E—sub-station fittings (transformers and switchboard, etc.); Section F—arc lamps and posts; Section G—meters; and Section H—overhead crane. Particulars are obtainable from Mr. Robert Hammond, Ormond House, Great Trinity-lane, E.C., on payment of £2. 2s, which will be returned on receipt of a bona fide tender. Tenders are to be delivered by August 24.

RESULTS OF TENDERS.

Bradford.—The Town Council have accepted the tender of Mr. G. A. Steinthal for the supply of two switchboards for the central electric light station for £185.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of July the receipts were £25,600.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,725.

Hereford—The National Telephone Company have decided to open a telephone exchange in Hereford.

Lanchester.—The Board of Guardians have decided not to adopt the electric light for the new infirmary.

Lytham—A start has been made with the construction of an electric tramway between Lytham and Blackpool.

Brompton.—The annual report of the Brompton Consumption Hospital states that the committee have decided to light the whole of the hospital by electricity.

Installation Work.—The Tayler-Smith Electric Company, Limited, are carrying out the installation of 6, Roland Houses, for Admiral Sir Windham Hornby, K.C.B.

Buxton.—Letters from the Welsbach Incandescent Electric Lighting Company and from the City of London Electric Lighting Company have been referred to a committee by the Urban District Council.

Rugeley.—The District Council have been discussing the question of lighting the town, and Mr. Seabrook, a member, suggested that they should utilise water power for electric lighting purposes.

Agency.—Messrs. Hodges and Todd, Hampstead-road, London, have appointed Messrs. W. McGeoch and Co., Glasgow, who will keep a stock of their electrical instruments, their sole agents for Scotland.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 11th inst. amounted to £1,578, as compared with £1,257 in the corresponding week of last year, being an increase of £321.

Change of Address.—Messrs. Russell and Lennard, electrical engineers and contractors, late of 22, Charing-cross, inform us that owing to pressure of work they have removed their offices to more commodious premises at 135, Victoria-street, Westminster.

Stafford.—In connection with the new electric supply station, the Town Council have appointed Mr. J. S. Highfield, of Clifton, Manchester, electrical engineer, at a salary of £120, and Mr. Dawson Clothier, assistant electrician, at a salary of £80 a year.

Digitized by Google

Aberdeen.—The electrical engineering business carried on by Messrs. New and Mayne, at 6, Schoolhill, Aberdeen, has been taken over by Messrs. P. C. Middleton and Co. Mr. Middleton was manager for Messrs. New and Mayne during the past two years.

Bournemouth.—The Winter Gardens Committee of the Town Council have recommended that in the lighting of the pavilion the large 500-c.p. lamps be removed and 16 c.p. lamps in groups of 18 lamps each be substituted. The recommendation has been approved.

Brighton and Rottingdean Seashore Electric Tramroad Company.—An extraordinary meeting of shareholders of this Company will be held at the offices, Madeira road, Brighton, on Friday, August 30, at 4 p.m., for the purpose of considering the issue of debentures and adopting a resolution thereon.

City and South London Railway.—The returns for the week ended August 11 were £860, compared with £897 for the corresponding period of 1894, being a decrease of £37. The total receipts for the half-year 1895 are £5,084, as compared with £5,203 for the corresponding period of 1894, being a decrease of £119.

Interruptions to Cables and Landline.—The following interruptions have taken place: cable, Brest-St. Pierre, Anglo-American Company, April 6, 1893; cable, Accra-Kotonon, August 12, 1895; cable, Accra-Lagos, August 12, 1895; and landline, Saigon-Bangkok, August 12, 1895. No repairs have yet been effected.

Bristol.—The Bristol Docks Committee held a meeting on Monday, when it was resolved, on the recommendation of the Sub-Committee for Works, to erect a signalling station near Sea Mills, for the purpose of facilitating navigation during fog, and to provide telephonic communication between such signalling station and the labourmaster's and dockmaster's offices.

Private House-Lighting.—Messrs. Rashleigh Phipps and Co. have recently received instructions to carry out the electric lighting of Lord Dudley's new house, 7, Carlton-gardens, and we understand, moreover, that they are at the present time exceptionally busy with the installation of a large number of private houses, etc., in the West-end of London and elsewhere.

Belfast.—The Electric Committee of the Corporation have met under the presidency of Alderman Sir Daniel Dixon. The resident engineer reported that the establishment under his control was in satisfactory working order. He also reported on the tenders for inspection plugs, referred to him at last meeting. Messrs. Richard Patterson and Sons' tender being the lowest, it was accepted.

Outing.—The employés of Messrs. Rashleigh Phipps and Co. had their annual outing on Saturday, 27th ult The party, comprising almost the whole of the staff, proceeded by an early train to Ramsgate, where they dined at the Cannon Inn. After dinner an interesting drive through Pegwell, Birchington, Margate, etc., was enjoyed, the proceedings throughout being characterised by great enthusiasm.

Phœbus Electric Battery Syndicate Limited.—This company has been registered by Mr. E. Pellas, Broad-street-avenue, E.C., with a capital of £3,000 to adopt an undetailed agreement for the acquisition of certain inventions in relation to primary batteries, and to carry on the general business of electrical and mechanical engineers, electricians, etc. Registered without articles of association.

Burton-on-Trent.—A meeting of the Town Council has been held, at which it appeared from the minutes of the Town Hall Committee that the report of the accountant on the examination of Mr. Churchill's account relating to the furnishing and electric light installation done jointly between Lord Burton and the Corporation showed there had been an excess of expenditure over the loan sanctioned of £259. 17s. 6d.

Meltham.—A meeting of the Urban District Council has been held, at which Mr. Allen Hollingworth, agent for Messrs. Jonas Brook and Bros. waited upon the Council and requested them to put down a new 2in. gas main to Meltham Hall, and also that the Council supply an adequate meter of from 80 to 100 lights. The gas, it transpired, was required to drive engines in connection with electric lighting machinery at the hall. The 2in. main and meter were granted.

Halifax.—At Monday's meeting of the Town Council, upon a resolution, moved by Alderman Brook, to authorise the expenditure of £1,000 for the purpose of supplying electric light to the district of Skircoat, Alderman Whitaker asked if the Council had had a sufficient number of applications from that district. Alderman Brook replied that they had applications from about 500 persons. He also explained that the proposed supply would not go further west than Heath-villas.

Snaefell Electric Railway.—It was expected that the new line of electric railway to the summit of Snaefell would have been opened for traffic on Saturday last, but in consequence of the delay which has taken place in erecting the overhead wires which supply the current, through the unfavourable weather of the last two weeks, the line will not be available for traffic before to-morrow (Saturday). The Board of Trade inspection by Colonel Rich and Major Cardew takes place to-day.

Cheltenham.—The Corporation are about to apply to the Local Government Board for sanction to a further loan of £10,000 for extension of mains and provision of additional machinery to meet the increasing demands for the energy. Three months ago there were 27 applications on the books, now there are 57. Some 2,160 8-c.p. lamps are already connected, and other applications in and coming in will bring the total up to over 3,000 lamps. The question of street lighting by electricity is under consideration.

Partnership.—Mr. G. L. Addenbrooke informs us that he has taken Mr. Ernest Scott into partnership. Mr. Scott served his time with Messrs. John Fowler and Co., Leeds, and was afterwards with Messrs. W. T. Goolden and Co., and the Brush Company, while for the last year he has been chief of the drawing-office department at the Electric Construction Company's works. Letters to the firm should be addressed to 21, Lichfield-street, Wolverhampton, but Mr. Addenbrooke will be frequently in London as heretofore.

Morecambe.—An extraordinary general meeting of the shareholders of the Morecambe Electric Light and Power Company, Limited, was held on Saturday evening to receive and consider a statement of the Company's affairs prepared by the secretary. After this had been discussed, it was resolved unanimously that the directors be empowered to treat with and enter into a binding agreement with the Morecambe Urban District Council, or any other intending purchaser, for the purchase and transfer of the Company's undertaking and property on the most favourable terms.

Keighley Electrical Engineering Company, Limited.—This Company has been registered, with a capital of £5,000, to acquire and take over as a going concern the business of the Keighley Electrical Engineering Company, Limited, of Bow-street, Keighley, to undertake all or any of the liabilities of the said Company on the terms and conditions set forth in the proposals in writing made for the old company by Arthur D. Smith, its secretary, and to carry on the business of electrical engineers, electrical suppliers of electricity, and manufacturers of and dealers in electrical apparatus.

Polyphase Currents.—Messrs. Johnson and Phillips have in hand the plans for another transmission scheme for the Barberton district. The power will be delivered by diphase currents at a distance of five miles from the power station, at which water power will be utilised to the amount of 120 h.p. The difference of potential at the generator will be 3,000 volts. The plant is to be used for air compressers to work rock drills for prospecting. Messrs. Johnson and Phillips have also in hand the St. Helens alternator, the alternators for the Cape Town and suburban lighting, the transformers for the Portsmouth extensions, and the transformers for the Bedford extensions.

Telephone Service for the West Riding Police.—The West Riding Standing Joint Committee have adopted the recommendation of the sub-committee to pay the National Telephone Company, Limited, £1,300 per annum for a private service of telephones for the purposes of the West Riding Constabulary, the materials and plant to belong to the company at the end of 15 years. At the end of that period the company will not object to renew the agreement for another 15 years on terms to be agreed upon for an annual sum to be paid to cover the actual maintenance, and they agree to the County Council extending the system to other police buildings than the divisional headquarters and the principal sectional stations named in the scheme.

Middlesbrough.—The Mayor (Alderman W. L. Taylor) presided at Tuesday's meeting of the Middlesbrough Council, when the Electric Lighting Committee minutes, which came up for adoption, recommended that a specialist be engaged, at a cost of not more than £50, to consider and advise the Corporation as to the best and most economical method of laying down electric light plant. Alderman Bulmer thought they should spend no more of the ratepayers' money, at all events at present. They had at present to meet a million and a half debt to pay interest and redemption on, and they should not further saddle the ratepayers. He moved that the minute be struck out. Alderman Sanderson seconded. After some discussion the minutes were adopted in their entirety.

Plymouth.—At Monday's meeting of the Town Council Mr. Bray, in moving the adoption of the Tramway Committee's report, commented upon the steady increase in the business done. Mr. Debnam reminded the Council that the Corporation of Portsmouth had decided to send a deputation to Bristol to inspect the electrical tramway works there, and asked whether it would not be advisable for that Council to adopt a similar course. Mr. Bray said they had received a communication from the contractor at Bristol, and he proposed to ask that a deputation from Plymouth might be sent to inspect the work. They, as a committee, before doing any work in Ebrington-street, should very seriously consider the advisability of adopting electrical power for a portion of their service.

Ipswich.—The Town Council have decided to experiment with incandescent gas burners for street-lighting. In the discussion on the subject, Mr. A. Cattermole elicited the fact that a contract for three years was to be entered into with the gas company, and urged that it would be more prudent to postpone the signing of such a contract until the Paving and Lighting Committee had reported upon the application which had been made for a provisional order by an electric lighting company. He moved as an amendment, therefore, that the consideration of this clause should stand over to the next meeting. The amendment was not seconded, and, in the course of conversation upon the matter, the town clerk pointed out that nothing could probably be done with regard to electric lighting, which would affect the public lighting of the town within the next three years.

Coventry.—A quarterly meeting of the City Council was held on Tuesday, the Mayor (Alderman Loudon) presiding. The Electric Light Committee recommended that rebates should be allowed to those consumers whose accounts are the most profitable to the

Digitized by Google

undertaking; the full price of 6d. per unit to be charged for all energy consumed in a half year up to a total equivalent to two hours' use per day of the maximum demand, and that all energy consumed beyond that total be charged at 3½d. per unit. Mr. Andrews opposed the recommendation, thinking that the true policy would be to charge a sufficiently high price to begin with, and then reduce the charge if found desirable. In the discussion it was stated that the plan had been found to prove remarkably successful at Brighton and elsewhere. The report was adopted.

Folkestone.—A Dover paper states that if the Dover Electric Light Company can make terms, as they propose, with the Corporation of Folkestone to supply them with the electric light, it will no doubt be an economical way of supplying that town, and will also be a good thing for our local company and for Dover generally. The Dover Electric Light Company have erected a station large enough to supply the whole of Dover, but, as a matter of course, with gas and other illuminants to compete with, they cannot expect to fully utilise their resources for several years, therefore it will be an improvement to Dover as a commercial centre for Folkestone to take their light from the Park-street station. Folkestone as a go ahead visitors' resort certainly needs the light, and it is clear that they could not obtain it at so little outlay in any other way.

Erdington.—A meeting of the Urban District Council has been held at which Mr. Dawson, a member, stated that since the last meeting he had made enquiries with respect to telephonic communication being established between Erdington and Aston. It would be remembered that an offer was accepted from the National Telephone Company to establish the communication at a charge of £25 per annum. He had interviewed Mr. Whitehouse, electrician, upon the subject, and had ascertained that it was possible to obtain telephonic communication of their own for about £50 and the charge for wayleave would only amount to £5 or £7 per annum. Mr. Whitehouse was prepared to submit a complete estimate of the cost of such communication to the Council at their next meeting. The Chairman said the Council and ratepayers were greatly indebted to Mr. Dawson for the trouble he had taken in the matter, and he moved that Mr. Whitehouse be asked to prepare an estimate. This was agreed to.

Blackpool.—A meeting of the Town Council has been held, at which the following minutes of the Electric Lighting and Tramways Committee were confirmed: July 23—Read, the following resolution of the Highway Committee on June 20, 1895: "That in view of probable future extensions of the Corporation's electricity works, all the central store-yard land between West Caroline-street and Princess-street, in this committee's department, be transferred to the electric lighting department on terms to be arranged." Resolved, that the Corporation be insured in the Law Accident and Contingency Insurance Society, Limited, against accidents from tramway cars and the permanent way of the tramways in the sums mentioned in the draft policy now submitted. July 25: That a sub-committee, consisting of the mayor, the chairman (Councillor Pearson), Aldermen Buckley and Bickerstaffe, and Councillors Heap and Smith, be desired to consider and report upon the best means of working electrically the Lytham-road tramways south of Station-road."

Cardiff.—A meeting of the Borough Council was held on Monday, when Councillor F. J. Beavan directed attention to the electric lighting account, which showed an expenditure of £5,053 in excess of the estimate, and pointed out that it was proposed to borrow £7,000. What, he asked, was to be done with the difference of nearly £2,000? It was explained that the added amount was for purchase of meters, extending mains, etc., and other requirements, the Mayor admitting that a statement to this effect ought to have appeared in the minutes.—At a ball given in honour of the "coming out" of Miss Edith Gibbons, eldest daughter of Mr. J. Skipworth Gibbons, of Boddington Manor, great satisfaction was given in the lighting arrangements of the grounds, conservatory, ball and supper rooms, etc., all of which had been carried out by Messrs. Knapman, Hodder, and Co, electrical engineers, Cardiff. For this purpose a dynamo, portable engine, and the necessary equipments had been brought into requisition.

Perth.—A meeting of the Town Council has been held, at which the town clerk submitted a letter he had received from the Caledonian Electric Supply Company, Glasgow, giving notice—in terms of the Electric Lighting Acts, 1882-88—of their intention to apply for a provisional order for the electric lighting of the burgh. The company hoped that the Corporation would be favourable to giving an opportunity of laying before them the terms they were prepared to offer. He (the town clerk) had replied, pointing out that the company had been too late in sending their intimation, which, in conformity with the Act, should have been made by July 1, and they had not answered his letter. On previous occasions the Town Council had disapproved of proposals to light the city by electricity, but probably it would only be courteous to allow the company an opportunity of lodging their terms. This would not, of course, preclude the Council from making objection to the application for a provisional order on the ground that timeous notice had not been given. The town clerk's suggestion was agreed on.

Machinery Insurance.—The Machinery Insurance Company, Limited, with a capital of £200,000 in 195,000 ordinary shares and 5,000 deferred shares of £1 each, has been formed to develop a system of insurance of machinery against partial or entire breakdown. The directors, at the outset, propose to confine the business to machinery alone, believing that in this department there is a well-nigh exhaustless field ready to their hands. A contract has been entered into with Mr. James Robert Fawkner, as vendor, whereby in consideration of the transfer to the company of the business of machinery insurance and maintenance, heretofore carried on by him, together with the goodwill, trade connections, policies in force, etc., the company agrees to pay to him the sum of £3,500 in cash, and to allot to him, or his nominees, 2,000 ordinary shares and 2,000 deferred shares of £1 each fully paid. The present issue is of 95,000 ordinary and 5,000 deferred shares. In Prof. Kennedy, F.R.S., president of the Institution of Mechanical Engineers, who has accepted the office of consulting engineer, the company will have at its command the advice and assistance of one of the first authorities in the science of mechanical engineering.

Colchester.—At the last meeting of the Town Council the Lighting Committee reported that the consulting engineer, Mr. W. H. Massey, had applied for a payment on account for his professional services, and the committee recommended that a payment of 30 guineas be made to him. Mr. Smith moved the adoption of the report. He said the committee were very anxious before coming to the Council with any scheme to thoroughly look into every suggestion that had been made as to lighting the town. They had had several conferences with and reports from Mr. Massey, who was still advising them, and the committee were unanimous in recommending this payment on account. Mr. Penney seconded. Mr. Beard said he noticed this was merely a payment on account. How far did the committee intend to go? Was there any particular amount specified, or was Mr. Massey "going to any extent?" Mr. Smith replied that Mr. Massey was not going to "any extent." He was advising the committee, and they knew that up to the present time his fees were very reasonable. Of course, as a non-professional committee they were not able to advise themselves on this subject, but it was not their intention to incur any serious liability in the shape of fees, and he again assured the Council that up to the present Mr. Massey's fees were very reasonable. The report was adopted.

The Mersey Railway.—At the meeting of the shareholders of this Company, held on Thursday last week, Mr. A G. Kitching, the chairman, stated that it would be remembered that at the last meeting power was given to the directors to promote a Bill in Parliament to obtain permission to use electricity or any other motive power on their lines, and also in connection with a scheme for a settlement with the various classes of debenture stocks, to raise £50,000 more capital. The debenture stockholders did not agree with the scheme proposed in the Bill to raise the additional capital, and that part of it was dropped, and all that now remained of the Bill was that relating to electricity, and that part was in a state of suspended animation, and what the new Parliament would do with it the directors did not know. He regretted to say that the directors had not been able to come to an agreement with the debenture stockholders. The Act required that three-fourths of each class of debenture holders should give their consent to any rearrangement which might be come to, and so long as the great body of those holders would consent to nothing which did not advantage them it seemed to him that the directors could do nothing. He was not aware that the question of electricity had been settled; personally, he was not in favour of electricity, but there was no harm in having a Bill authorising them to use electricity as a means of locomotion, should the shareholders think fit to adopt it.

Music-Hall Lighting.—Collins's Music Hall, Islington green, has just been entirely redecorated, and amongst the many improvements which have been introduced that of lighting the hall by electricity stands foremost. This part of the work has been carried out entirely by Messrs. Vaughan and Brown, Limited, of 16, Kirby-street, Farringdon road, in 21 days from the date of commencement, the time for doing the work being of necessity very short, as it was imperative that the hall should reopen on Bank Holiday evening. The current was, we understand, promised by the Vestry for that date, but as their electricity supply works were not ready, the proprietor (Mr. Herbert Sprake) decided at the last moment to have a temporary plant laid down. Five days before the opening night, Messrs. Vaughan and Brown, Limited, undertook to supply and fix the plant and have it running on the night in question. This they succeeded in doing, having in the meantime put in a 65-h.p. engine and a large dynamo in a small space at the back of the hall. The electric light fittings are also supplied by the above firm. They were all specially designed for the hall, and manufactured at Messrs. Vaughan and Brown's works. The firm's search-light is worked from the roof of the theatre, and throws the rays of light down on the artists, producing a beautiful effect, and does away entirely with the lime-lights in the wings and the use of gas. We understand that the same firm are both lighting and heating, etc., the Bath Pavilion and the Bristol Empire, and also that they propose bringing out very shortly a new arc lamp.

Electric Clocks.—We have received a circular relative to the system of electric clocks which has been brought out by the Synochronome Company (F. Hope-Jones and G. B. Bowell), Birkenhead. Instead of a number of separate clocks requiring weekly attention, whose pendulums rarely even pretend to be accurate timekeepers, there is in this system but one pendulum which requires no attention and is capable of keeping time to within one second per month. It is usually placed in the hall, and the time it records is indicated by clock faces wherever desired. They may be placed on the mantle-shelves of the various rooms, or suspended on the walls with flexible cord, as the absence of mechanism enables them to be treated artistically, and suggests their combination with drawing-room art-work in wrought iron and wood carving. If desired, this simple electric movement can be

Digitized by Google

fitted into any existing clock case, and striking or chiming may be accomplished by all or any of the dials. The necessary wiring is more simple than that for electric bells, being only the connection of one dial with another by a single line. For putting forward the hands of all the dials a push button is provided on one of them. For setting back it is sufficient to move the hands of this dial only, and all will be altered. When Government telegraph, telephone, or railway time signals are available the one pendulum may be automatically synchronised, and thus every dial will represent Greenwich mean time. The pendulum is kept in motion by two wheels and an electromagnet which derives its energy from a small dry cell.

Bangor (Wales).—A meeting of the City Council has been held, when the minutes of the meeting of the Electric Lighting Committee held on the 24th ult. were read. They stated that Mr. Medhurst was present and presented his amended report and estimate as to the proposed electric lighting works, which we give in another part of this issue. After duly considering same, it was proposed by Dr. H Grey Edwards, seconded by Mr. Robert Hughes, and unanimously resolved that the committee, having carefully considered the question of lighting the borough with the electric light and called to their aid Mr. Medhurst, electrical engineer, of Westminster, London, recommend the Town Council to apply for a license with the least possible delay, and that the committee be empowered to take whatever steps it may find necessary to carry out the scheme as suggested by Mr Medhurst in his report. Mr. Thomas Lewis, chairman of the committee, said he was sorry to say that the further he went into this matter the less inclined he felt to go on with it, and he therefore could not move the adoption of the minutes. Dr. H. Grey Edwards had great pleasure in moving the adoption of the minutes. Something must have occurred since the committee meeting to account for Mr. Thomas Lewis's astonishing action. Proceeding, Dr. Grey Edwards said that the committee had written to some 25 towns, some of which were corporations holding gasworks, for information as to the working of the electric light system in those places, and he thought that almost without exception they had received favourable replies. Mr. Robert Hughes seconded the motion. After some discussion, it was decided to refer the matter back to the committee.

Bradford.—At Tuesday's meeting of the Town Council, Mr. W. C. Dixon (chairman of the Gas and Electricity Supply Committee) moved the adoption of the minutes of that committee, which included resolutions approving the plan of a proposed extension of buildings at the south end of the electricity works, and accepting tenders for all the work amounting in the aggregate to the sum of £304. 13s 9d.; accepting the tender of Mr. G. A. Steinthal to supply two switchboards at the electricity works for the sum of £185; appointing Mr. Alfred H. Gibbings as electrical engineer at a salary of £300 per annum; advancing the salary of Mr. Dalton, assistant engineer in the electricity department, from £150 to £180 per annum; and accepting tenders for the supply of cannel and gas coal. Mr. Dixon said the extension referred to in the minutes was for the purpose of putting in two new boilers which could not possibly be got in, to allow any room for working, unless the enlargement of the premises took place. Mr. Dalton had been one of the applicants for the appointment of electrical engineer, and though the committee had not thought fit to appoint him they were satisfied that he was fully deserving of the increase of salary which was mentioned in the minutes. The resolution was seconded by Mr. James Kay. Mr. M. O'Flynn asked if the boilers which had been lately introduced into the works had given general satisfaction. Mr. Dixon said the new boilers referred to by Mr. O'Flynn were working so unsatisfactorily that the town clerk had had to threaten the firm who had provided them with proceedings if they did not at once put them into proper working order, so that they would fulfil the purpose for which they had been purchased. The minutes were adopted.

York.—A quarterly meeting of the York City Council was held on Monday night, the Lord Mayor (Alderman Wm. McKay) presiding. The Streets and Building Committee acting as the Electric Lighting Committee recommended the Council to accept the offer of the Electric Construction Company, Limited, for the supply of the first instalment of the plant, together with their offer to run the plant for a period of seven years. The tender is for the alternate-current system, and the essential points of the Oxford system are applied to alternating currents. Alderman Ager, in moving the adoption of the report, said the amount of the tender was £8,650, with an addition of £6,000 outlay for buildings, etc. The company offered to run the plant for a period of seven years, paying 6½ per cent. on the capital outlay, and agreeing to charge a sum of not more than 6d. per unit. The motion was seconded by Mr. Mann, who pointed out that the terms of the specification prevented any possibility of the scheme being a burden upon the ratepayers. The system would enable any part of the city to be supplied from one station, which it was proposed to build on the Foss Islands. Alderman Wragge though the system the Council was asked to adopt was the very worst that could possibly be proposed. Mr. Purnell maintained that the sanction of the Council was being asked to a scheme which the members of the committee did not understand themselves. He warned the Council against its adoption. Mr. Scott moved an amendment referring the matter back, with the object of taking the opinion of Prof. Kennedy as to the best system to adopt for the city; and the amendment was seconded by Mr. Mansfield and supported by Mr. Challenger. Mr. O'Connor having spoken in favour of the recommendation of the majority of the committee, Mr. Purnell argued that the various schemes which had been laid before the Council should have been considered as to economy and efficiency. The discussion was continued by Alderman Wragge, Mr. J. S. Grey, and Mr. Mann, after which the amendment was put to the vote, when only 3 voted in favour, 23 against, and 7 were neutral. The amendment was therefore lost. Alderman Wragge then moved as an amendment that the consideration of the matter be adjourned until the second Monday in October, but the amendment was negatived. Another amendment was proposed by Mr. Shafto to the effect that the matter be referred back to the committee, that they agree upon an expert who shall report as to the best mode of electrically lighting the city, advertise for tenders, and report to an early meeting of the Council. The amendment was carried.

Islington.—The Vestry have held a meeting at which the clerk reported a series of communications from the solicitor to the London County Council on the subject of the electric lighting loan of £51,000. It was agreed to accept the terms proposed by the Council, amongst which were the following: That the Vestry undertake not to raise during the currency of the loan any fresh amount to cover the same work; the rate of interest to be 2¾ per cent.; the loan to be spread over 42 years; and the Vestry to provide for all renewals during that period out of a sinking fund to be provided for the purpose. The amount estimated to be required for the purposes of the lighting rate is £9,032, an increase of £1,790 upon the current half-year's rate. The greater part of this addition is occasioned by the increased cost of lighting the public lamps in the "compulsory area" by electricity instead of gas. It is anticipated that the new system of lighting will come into operation about the middle of November next, the increase, therefore, covers a period of about 4½ months. A report was received from the General Purposes Committee stating that it had considered the question of the wiring and fitting up to the Vestry Hall and offices, for the purpose of lighting the same by electricity, and in connection therewith an estimate of the cost and a specification prepared by the electrical engineer; submitting such specification for the approval of the Vestry, and recommending that it be adopted; and that the committee be authorised to invite tenders upon the basis thereof, and to enter into a contract for the carrying out of the work at an estimated cost of £311 for the work set out in Schedule 1 of the specification; and at a further sum of not less than £20 for the work mentioned in Schedule 2, according to the design and workmanship decided upon as being most suitable. This was agreed to. A report was received from the Finance Committee stating that pursuant to Vestry reference of May 24 last, respecting the electric lighting loan of £51,000, it has submitted a case for the opinion of Sir Richard Webster, Q.C., and Mr. A. Macmorran, and they having advised that notwithstanding the provisions contained in Sections 190 and 191 of the Metropolis Management Act, 1855, the London County Council must be assumed to have a discretion as to the granting or otherwise of their sanction to a loan, the committee is of opinion that the Vestry should, under the circumstances, accept the alternative offer of the Council to lend the whole of the money for a mean period of 42 years on the condition that if any portion of the machinery or plant covered by this loan requires to be renewed during its currency, such renewal shall not be made the subject of a new loan, and on the further condition that the rate of interest be 2¾ per cent. per annum, and that the loan be taken up on the "annuity" principle, and recommended accordingly. This was agreed to.

Wigan.—A meeting of the Town Council has been held, at which Alderman Ackerley enquired if anything was being done with regard to the electric light. Mr. Holmes, the chairman of the Electric Lighting and Gas Committee, said he was afraid the electric light was snuffed out for a time. It was very much against his will. He thought the sub-committee were making a great mistake in the action they were taking, but he could not sit in judgment upon them. Unless they got the unanimous feeling of the sub committee he did not wish to proceed. If it were a question of a majority he had every reason to believe they could carry it, but he desired the whole committee to be in union and harmony. He hoped it might be soon. The committee might perhaps be taking the right course, but to him it did not appear to be so. Mr. Fyans thought that, notwithstanding that the small committee could not come to a unanimous verdict, the town or those directly interested in its institutions desired that the thing should be pushed forward. Look at the money they had spent in decorating that room, and at the free library with its priceless treasures, which would not only lose their lustre in a few years, but would get in a deteriorated state. Were they to understand that because one or two gentlemen on that sub-committee did not see eye to eye on the expediency of introducing the electric light, the Council were not to have the opportunity of casting their vote upon it? He said most unhesitatingly that the Council would unanimously support the action of the majority of the sub-committee. The introduction of the light might entail a little higher rate, but it would be of such an immense benefit to the local institutions, give facilities to tradesmen for advertising and making Wigan brighter and more important, so that it was worth the venture. If it was delayed much longer they would be giving other people the opportunities they possessed, and he promised that at the next meeting of the Council he would raise the question. Alderman Phillips said he knew there were important works of decoration waiting to be done, but the parties would not proceed because the electric light had been promised. When they saw the effect of the light in other towns, how it set off the shop windows, he felt they were behind hand, and he believed the chairman would have the support of the Council in carrying the work through. Mr. Johnson felt certain that if they delayed it

Digitized by Google

much longer they would have private competitors. The matter should be pushed forward. He thought he knew why the chairman had not brought it on, but he should have another trial. Mr. Laycock felt sure it would come as a surprise and disappointment to manufacturers and business men that they were not as yet to have the electric light. He hoped the sub-committee and Gas Committee would take the matter in hand again, so that they could have in Wigan what was already common to most towns. Mr. C. B. Holmes' opinion was that the discussion must have the effect of giving the committee confidence to push forward with the matter. He could assure them that some three or four months ago they were anxious to proceed with the erection of the necessary buildings, so as to have them dry and in readiness for the reception of apparatus and engines.

Dublin.—A deputation representing the ratepayers residing in the neighbourhood of Earl-street waited on the Dublin Corporation on Monday to urge upon the Council the advisability of the Corporation granting the request of the tramway company to extend the electric tram system from Annesley Bridge to North Earl-street and Nelson's Pillar. Mr. Nagle strongly urged the prayer of the petitioners, and pointed out that all the inhabitants and frontagers along the line were most strongly in favour of the extension of the electric traction system. The deputation had the greatest possible confidence in the judgment of the members of the Council, and it would leave this question with the greatest confidence in the hands of the house. Mr. William Lawrence and Mr. V. O'Brien, as frontagers in O'Connell-street, supported the prayer of the petition. The Lord Mayor pointed out that the Corporation did not in the slightest degree oppose the introduction of the electric traction system. He himself was much in favour of it, but it should not be forgotten for a moment that the duty of the council was, whilst not opposing such an extension, to see that proper conditions should be imposed. They should ensure that proper and adequate conditions should be imposed—whether by way of rental for the benefit of the city, or whether by way of accurately defining the conditions under which the tramway company were to run their system. These were matters for future consideration. The tram company would appear to be desirous of erecting posts, wires, and everything they desired, and of practically taking possession of the streets to that extent. He was in favour of the electric tram system, and they should give the company every facility, which they were prepared to do. But within their own domain the Corporation were masters, and should not allow any other body to take control over their streets. There should be a clause in the Tramway Act providing that no system of electric tramways should be run without the consent of the Corporation. He believed that in this matter they would be supported by the Council and the citizens, and that they would not allow the tram company or any body to get further running powers or leave to erect poles, etc., without the absolute consent of the Council, and if the tramway company would introduce before the Lords the clause that the Corporation suggested, no doubt they would soon see the electric trams running in the streets the deputation spoke of. Mr. Little rose to order. He thought the Lord Mayor should in this matter take the Council into his confidence. They should hear the members of the deputation, and then allow them to go, and discuss the question at the Council. The Lord Mayor had only expressed his own personal view. The Lord Mayor said his observations were perfectly in order. He had expressed no opinion that he did not think would be shared in by every member of the Council. He hoped and believed that the city would support them, and he could only repeat that they did not oppose this extension of electric traction—quite the contrary—but the Corporation were to be the judges of what the proper system was. Mr. Clancy said they were not in favour of overhead wires. Mr. Little said it was an unusual thing for the views of the Council to be put before a deputation by the Lord Mayor. The Lord Mayor said he simply desired to convey what was the opinion he believed of the house. Mr. Nagle said he had to express the hearty thanks of the deputation for the kindness with which they had been received. As he stated at the close of his opening observations, they had the fullest confidence in the Corporation. Mr. Lawrence also conveyed the thanks of the deputation, the members of which then retired. The Lord Mayor subsequently moved the adoption of a report of a committee of the whole house having reference to the Dublin United Tramways Bill, 1895. It only recommended the reappointment of the committee, the reason being that in the course of the enquiries that had already taken place before the committee it had appeared desirable that the relations between the tramway company and the Corporation and the construction of the various Tramway Acts should be further investigated. Opinions on the subject had already been taken from Mr. Carton, Q.C., and Mr. Fitzgerald in London. Mr. Kennedy seconded the motion, which was agreed to.

Weybridge.—The Urban District Council have held a meeting at which the Highways and Lighting Committee reported that at one of their meetings, Mr. Bilney read a report on behalf of the committee appointed to inspect the Weybridge Electric Lighting Company's works, and it was proposed by Mr. Till and seconded by Mr. Brown, that, in the opinion of that committee, it would not be to the interest of the ratepayers either to buy the works of the Electric Light Supply Company or to invest the public money in any scheme for lighting the district. An amendment was proposed by Mr. Ward and seconded by Mr. Bilney, that it was desirable that the public lighting of that parish should be in the hands of that Council. The amendment was put, and negatived by five votes to three. The original motion was therefore carried. It was further proposed by Mr. Ward and seconded by Mr. Rowland, that the Council purchase standards and lamps for lighting with oil temporarily. This was carried *nem. con.*, and it was resolved that the surveyor report as to the number of standards required. At a further meeting of the committee, Mr. Bilney informed the members that at his request Mr. Spagnoletti, electrical engineer, was in attendance. It was proposed by Mr. Till, and seconded by Mr. Jarvis, that as the subject of buying the electric lighting works by the ratepayers had been decided in the negative it should not be again discussed by the committee. An amendment was proposed by Mr. Ward, and seconded by Dr. Powell, that the matter be re-opened and Mr. Spagnoletti heard. The amendment was carried, and Mr. Spagnoletti made a statement respecting the appliances that would be required, and the probable cost of maintenance. It was then proposed by Mr. Ward that in order to free the Council from taking the responsibility of charging the ratepayers with the cost of purchasing the present electric lighting works a meeting of the inhabitants be called by the chairman of that Council and the views of the inhabitants taken upon it. This was seconded and carried *nem. con.* It was proposed by Dr. Powell, seconded by Mr. Ward, and resolved that Mr. Spagnoletti be asked to prepare the scheme and specification and give an estimate of the cost of the proposed works. It was resolved that if the proposed works be not carried out, or if Mr. Spagnoletti be not appointed the engineer for carrying out the same, a fee of 25 guineas should be paid him. The chairman was about to put the recommendations of the committee to the meeting, when Mr. Brown proposed that the report of the expert be read. Dr. Powell seconded and the motion was carried. Mr. Spagnoletti's report was then read by Mr. Bilney. It first stated that with reference to the additional plant required to double the output from the Weybridge electric light central station, he thought it highly desirable to put down any additional plant as similar as possible to that now erected. With regard to the financial outlook of the undertaking, he considered that it was thoroughly satisfactory, as electric lighting companies generally were in a flourishing condition, and he thought that in the course of a year or two the public lighting would be able to be paid for out of the profits accruing from the private lighting. The electric light was in many places in the hands of corporations and district councils with excellent results. The street lighting of Weybridge would under the latest scheme require 154 lamps, and hitherto the sum of £2. 17s. 6d. per annum had been paid for each, making a total of £442. 13s. per annum. The lamp revenue from the present consumers was £400, and taking the public lighting at £2. 17s 6d. per lamp, which the Council would have to pay, showed an amount of £842. 13s, at which figure he thought the station would pay expenses, and, as the private consumers increased, the profits accruing from their consumption could go towards paying for the street lighting and thus reduce the rate. They might say the purchase of the station would cost £3,000, and the various new requirements would work out to £6,664. 5s. Then the estimate for the new street lighting circuit was as follows; 35 posts at a cost of £5. 12s. 6d., £196. 17s. 6d., and labour, etc., £300, giving a total of £496. 17s. 6d. To this must be added an amount for cable, which would depend upon the tender accepted; but they might say the whole cost of taking over the present works and laying down new machinery, etc., would amount to something over £8,000. The Chairman asked whether the Council would approve of the minutes of the committee, and the majority voted in favour of their approval. A public meeting has also been held to consider the lighting question, and this was followed by a special meeting of the Urban District Council, which went into committee to deal with the matter.

Proposed Derbyshire Electric Light Railway.—A meeting of gentlemen interested in a scheme for an electric light railway from Derby to Ashbourne, was held at the St. James Hotel, Derby, on Friday last, to consider the desirability of adopting suggestions contained in a report on the subject prepared by Mr. John Shaw, jun. The Chairman (Mr. C. E. Newton) said that although he did not live on the route it was proposed the railway should take, he took a very deep interest in the scheme. He thought there was a very real need for such a scheme, and that it was extremely desirable that communication between Derby and Ashbourne should be greatly improved, seeing how far round the existing railway went, and what a long time it took to cover the distance. Whether an electric railway was the best—and he really thought Mr Shaw had hit upon the right idea—or not was another matter. He had seen several electric tramways at work on the Continent and had very frequently travelled by them. He would not dare to give an opinion on the feasibility of the proposal of Mr. Shaw, but he considered some such scheme exceedingly desirable. Mr. Shaw then read the report he had prepared, of which the following is a digest: "To build and work an electric (light) railway on the overhead electric system as the method of traction, as compared with other various methods that are at present at work—viz., cable, electric accumulators, steam, and horse—has been proved to be the cheapest and most suitable. The cost of running per car mile by the overhead system, including all expenses, with the exception of guards' wages and maintenance of permanent way, is 4·06d., as against 8 57d. by steam. It is proposed that the line should be connected with the existing Derby tramway, which terminates on the Ashbourne-road. Thence it would run through Mackworth, Kirk Langley, and Brailsford, into the town of Ashbourne, terminating near the bridge. On only one portion of the line is there a really stiff grade, and that is for a mile at the Ashbourne end; but there is not any difficulty in getting over this. It is suggested that the line should be laid on the western side of the road, through nearly the whole length, as there is ample room. Through the villages it would probably have to run down the centre. There

Digitized by Google

are telegraph poles placed at the side of the road, but there would not be any difficulty in obtaining power to remove these at a small cost. It has already been stated that it is proposed to use the overhead electric system. There are several of these, but the side wire system, as already in use in South Staffordshire, is without doubt the best, and it is recommended that it should be used in this case. The permanent way could be laid out at a cost of about £2,000 per mile. Paving would only be laid where absolutely required by the authorities. In all probability it would only be insisted upon through the villages and a small portion at each end of the line—viz., in Derby and Ashbourne. Electric signalling would be adopted to enable the crossings to be placed at as great a distance as possible from one another. Turnouts and fixed stopping places will be made where necessary, but a car could stop anywhere to take up or set down. The railway company average about 1¾ hours to run from Derby to Ashbourne (if punctual, which they very seldom are), and if the cars on the proposed electric railway are run at a maximum speed of 15 miles an hour and a mean speed of 10 miles an hour the journey could be completed in an hour and 15 minutes, thus showing a saving upon time between the light railway and the ordinary railway. The rolling-stock necessary for a line of this kind would consist of motor cars, trailers, and goods cars. A motor car would have to be equipped with motors of 20 e.h.p. each. These cars would cost approximately about £600 each. Trailing cars, which would only be used in summer, would cost about £200 each. The goods cars specially fitted up, would cost about £100. All the cars would be lighted by electricity. It is proposed to build the generating station near the Brailsford Brook, about 7½ miles from Derby, as that seems to be the best site, the heaviest part of the road being at the Ashbourne end. If sufficient hydraulic power could be obtained from the brook a large saving might be made in generating the current. The following is a rough estimate showing the cost of the line: Cost of permanent way, including materials, laying, etc., £25,600; overhead equipment, £18,600; generating station, including land, buildings, engines, etc., £12,000; rolling-stock, including six motor cars, six travelling cars, and six goods cars, £6,100; total, £62,300. The maintenance of the line would be very small, and the assistance it would be possible to give to the County and District Councils in delivering road materials would approximately pay for the maintenance." Mr. Shaw said that he had received a further estimate from Mr. Dickinson. It was to the effect that there would be 19 230 journeys made per annum, and that the mileage would be 250,000 per annum. The cost would be about 6d. per mile, or a total of £6 250 per annum. The population of the district was about 105,000, and assuming—as was quite reasonable—that the number conveyed annually reached that figure, the income from passenger traffic only would come to £18,800, which would leave a balance on the right side of £5 550. With regard to traffic along the road, 600 traps had been counted through the Mackworth Toll Gate on one Friday. After some discussion Mr. Holland moved that a committee be appointed to consider the question and report to a future meeting, the committee to consist of the following: Messrs. C. E. Newton, G. Meynell, T. O Farmer. J. Smith, Gilbert Murray, Edwards, R. Finney, Tomlinson, J. Pakeman, and W. R. Holland. Mr. Pakeman seconded, and the resolution having been agreed to, a vote of thanks to the chairman concluded the proceedings.

PROVISIONAL PATENTS, 1895.

AUGUST 6.

14801. **Improvements in the electrolytic production of oxides and salts which are insoluble, or practically insoluble, in the electrolyte.** Carl Lucknow, 70, Market-street, Manchester. (Complete specification.).

14804. **A combined electric bell press, pear press, and holder.** Osmond Yeadon Rhodes, 16, Grange-terrace, Chapeltown-road, Leeds.

14840. **Spray electrolysis.** Frederick William Durham, jun., Glenham Lodge, Station-road, New Barnet, London.

14842. **Improvements in electric condensers for use in polyphase and multiphase alternating-current circuits.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles S. Bradley, United States.) (Complete specification.)

14847. **Improvements in electrically-insulated pipes, and in the method of joining the same together, and in insulating cement or enamel used in connection therewith.** Alfred James Perton Whitaker and Frederick Gwilym Treharne, 45, Southampton-buildings, Chancery-lane, London.

14858. **Improvements in electric meters.** Jesse Harris, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

AUGUST 7.

14902. **Improvements in plates for secondary batteries.** Giuseppe Fabbro, 1, Queen Victoria-street, London.

14914. **Improvements in overhead conductors for electric railways and tramways.** William John Brewer, 15, Victoria-street, Westminster.

14937. **Improvements in electric block-signals for railroads.** Angus Cameron Gordon, 52, Chancery-lane, London. (Complete specification.)

AUGUST 8.

14973. **Improvements in prepayment apparatus for attachment to gas, electricity, or other fluid meters.** Wesley Webber, 4, South-street, Finsbury, London. (Date applied for under Patents, etc., Act, 1883, Section 103, April 16, 1895, being date of application in United States.)

AUGUST 9.

15024. **Electrolytic production of amalgams, and their utilisation.** Emile Andreoli and Gabriel Andreoli, 18, Somerleyton-road, London. (Complete specification.)

15057. **Improved means and apparatus for regulating or compensating for the variation of voltage in electric circuits.** Siemens Bros. and Co., Limited, and Henry Simpson Sayer Harvey, 28, Southampton-buildings, Chancery-lane, London.

AUGUST 10.

15069. **Improvements in and relating to telephony.** John Stuart Biggar, 70, Market-street, Manchester.

15114. **Improvements in electric current meters.** Carl Erben and Emanuel Bergmann, 18, Buckingham-street, Strand, London. (Complete specification.)

1 119. **Improvements in electrolysing apparatus.** Louis Achille Georges Emmanuel Roger Comboul, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

18938*. **Incandescent lamps.** Langhans. (Amended specification.)

1894.

16473. **Telephones.** Ritter.

16943. **Ladder platform for telephone linesmen, etc.** Langlois.

17077. **Lenses and electric lamps.** Dando and Gwynne.

17542. **Electric storage batteries.** Liardet.

17808. **Arc lamps.** Lyon.

18999. **Electric fuses.** Thompson. (Société M. Gaupillat and Co.)

1895.

1512. **Arc lamps.** Ross.

7656. **Telephone apparatus.** Boult. (Rabbidge.)

8385. **Wire gauze brush for dynamos, etc.** Soar and Collier.

11752. **Electro-deposition of gold and silver.** Andreoli.

NOTES.

Mining Institute of Scotland.—A meeting of this institute has been held in Edinburgh at which Mr. Mitchell, the president, read a paper on "Electric Coal-cutting at Glencleland Colliery."

Industrial Exhibition.—A National Trades and Industrial Exhibition is to be held in the East End Exhibition Buildings, Glasgow, opening in November next, for about three months.

Telegraphy in India.—It has been decided to construct a direct telegraph line between Madras and Bezwada, and the work is to begin as soon as possible. The first section on the railway line between Royapuram and Ennori should be ready for traffic in September next.

Electric Traction in Egypt. — The American Consul-General at Cairo reports that street railways with electric traction are promised for Cairo next year, the concessionees being Belgians, and Alexandria is expected soon to follow suit. There are several bidders for an electric tramway from Cairo to the Pyramids, a distance of 10 miles.

The Falls of Foyers.—In the House of Commons on Friday last Mr. A. J. Balfour, asked by Dr. Farquharson whether he would take steps to prevent the destruction of the Falls of Foyers by an aluminium company, said he could add nothing to the statement made by the late Secretary for Scotland in May that to deal with the matter was beyond the power of the Government.

The Patent Office.—By reason of instances of mutilation of books within the institution, a warning from the Comptroller-General has been displayed about the rooms, to the effect that any person convicted of the offence is liable to six months' imprisonment. Also a notification is appended containing a threat of the withdrawal of the present facilities for reference should such malpractices continue.

New Telegraph Steamer.—Mr. A. R. Brown, the consul for Japan at Glasgow, has just placed with Messrs. Lobnitz and Co., of Renfrew, an order for a large twin-screw ocean-going telegraph steamer, completely equipped for laying, picking up, and repairing telegraph cables. It is to be hoped that this is the first of the orders which it is understood the Japanese Government contemplate placing in this country.

Electrolysis of Ores.—The electrolytic separation of metals from their ores is accomplished by first reducing the crude ore chemically to salts capable of being electrolysed. Different salts of the same metal, treated by different methods, yield to electrolysis with different degrees of facility, and produce the metal in varying degrees of purity and in variable quantity with the same current. On the nature of the preliminary process, therefore, depends the success or failure of the results. Among the various ores reduced in this manner are those of zinc, lead, copper, silver, gold, aluminium, sodium, and magnesium.

The Pacific Cable Scheme.—A proposal has been submitted to the Hawaiian Senate by Mr. Spalding for the laying of an American cable between California and Honolulu. The proposal requests the payment by the Hawaiian Government of an annual subsidy for 20 years of 50,000dol., exclusive of the cable franchise. It is doubtful what decision the Hawaiian Government will adopt in the matter. A Reuter's telegram from Honolulu, dated August 14, says: "The Bill for the construction of a cable between California and Honolulu was passed to-day. The annual subsidy was fixed at 40,000dol. for 20 years. The construction of the cable now depends on the obtaining of a subsidy from the United States Government."

New (?) Incandescent Lamp.—The German Patent Office, usually so alert, must have been caught napping when it recently granted a patent to Herr J. Wende, of Driesen, for an incandescent lamp which is described as follows: "The lamp consists of a round glass globe with two orifices on opposite sides, through which the electrodes are carried. The straight carbon filament is cemented to the electrodes. The side openings are fitted with metallic sheaths, and small screws secure the connection to the leads." Herr Wende also makes lamps on this principle with cross (+) filaments. But Bernstein introduced lamps of this kind many years ago, and the carbon filament was probably better arranged than in the Wende lamp.

Accidents in Mines.—Mr. Austin Kirkup, in his prize essay on "The Prevention of Accidents in Mines," observes that there is no doubt that the legislative enactments in connection with mines have had a most beneficial effect on the safe working of collieries. He thinks that too much attention has been given to providing a lamp which will be safe in explosive currents, which are seldom, if ever, met with in mines, and too little attention has been given to the improvement of the luminous power of the lamp, which is a very important matter. We certainly need more light in mines, but with the present system of oil safety lamps any improvement appears to be impossible. If the electric light could be combined in a portable form with a gas detector, the acme of success in the lighting of mines will have been attained. It is for those who are interested in the safe working of collieries to solve this problem.

Light Railways.—On Wednesday, in the House of Commons, on the vote for £42,495 in connection with tramways and light railways in Ireland, Mr. Strachey moved a reduction of £17,717, the proposed increase during the financial year. He pointed out that this policy of State-aided railways was not applied to England and Scotland. If it was a good system for Ireland, it was also good for other parts of the United Kingdom, and he objected to any further increase of the grants till all parts of the kingdom were allowed to participate in the benefit of these lines. After some further discussion, Mr. Balfour said this question, like other questions for the benefit of agriculture, would be considered by the Government, and, if there was public money available, they would consider how it could best be applied to the object suggested by the hon. member. After some further discussion the amendment was negatived without a division, and the vote was agreed to.

Electric Meter Competition.—The Royal Scottish Society of Arts, of 117, Great George-street, Edinburgh, offers for competition a Keith prize, of £50, for improvements in electric energy meters for domestic supply. Competitors must send a description, with working drawings, and a meter adjusted for a mean pressure of 115 volts and for a maximum of 4,000 watts. Preference will be given to meters suitable for alternate as well as continuous currents. Special importance will be attached to the minimum load at which the meter can register correctly, and to the energy absorbed by the meter when the consumer is using a light load or is taking no energy at all. The error should not exceed 2 per cent. at any load; error due to changes of temperature between 0deg. C. and 30deg. C. should be specified. The competitors must send in their papers, etc., not later than May 1, 1896. Their claims must be limited to recent improvements.

A Pin for the Shahzada.—By special invitation of the Shahzada, Mr. W. H. Abdullah Quilliam, Sheikh-ul-Islam of the British Isles, and Moulvie Mahomed Baraket-Ullah, journeyed to London to take final leave of his Highness Prince Nasrullah Khan, who is about to depart from England. They were the bearers of two valuable articles to be presented to the Shahzada. They consist of a valuable keyless gold centre seconds chronograph hunting Liverpool-made lever watch, and of a pin to be worn in a turban, or Afghan hat, and is constructed entirely of the rare metal glucinum, better known as the metal of the emerald, and is only obtained from that particular species of precious stone by a lengthy chemical process, being finally freed by or released by means of electricity. This interesting article of scientific jewellery has been designed and constructed entirely by Prof. H. Nazrullah Warren, lecturer on chemistry, electricity, and metallurgy at the Liverpool Muslim College, in his private laboratory, 18, Albion-street, Everton.

Electricity in Turkey.—It seems that the Sultan has so far torn himself from the prejudices of his people against having anything to do with that heathenish discovery of the giaours, electricity, as to permit his Ministry of Marine to conduct at Ismidt a series of experiments with electrical projectors, which have apparently resolved themselves into a competition between the respective productions of Messrs. Schuckert and Co., MM. Sautter, Harlé, and Co., and M. Breguet, of Paris. Which projector was victorious we know not—the Turk is noted for his "unspeakableness." But the question of the introduction of electric lighting into the country of the Osmanli is on an altogether different footing, for while the Sultan's advisers are understood, under a heavy pressure of bakhshish, to be willing to place the matter before the Caliph in a favourable light, so to speak, the fact that some of the members of the Royal family are extensive shareholders in the local gasworks is considered to be a sufficient guarantee that electricity as an illuminant will make no headway in Turkey for some time to come.

A Gas Man on the Electric Light.—Mr. George Livesey, in addressing the shareholders in the South Metropolitan Gas Company, stated that he had "never before said a word from that chair about the electric light. That form of illumination had gained no footing whatever in their district. They had not shown any antagonism towards it. Indeed, on the contrary, they had given the electric light people every facility for laying the mains; but in the result, instead of being thankful, they were turning a bit spiteful, and this feeling was dragged in in connection with the company's profit-sharing business. In one of the journals devoted to the electric light interest the following observations occurred: 'We wonder if gas companies do this? Their consumers' meters always seem to run very fast, as though trying to outrun the works' meter. . . . They have such means of squeezing another 10 or 50 per cent. out of the public by increased charges, or saving at the works by reduced cleansing of the gas, or by a reduction of lighting power, that the great bane of profit sharing—viz., a year with a loss—never occurs?' That amused him, because it was well known when people got spiteful it was a proof that they were losing!"

Type-Setting by Electricity.—Many people were of opinion that the "Linotype" had done all that it was reasonable to expect, for some years to come, in the way of a type-setting machine, the *Financial Post* says. But this appears not to be the case; for wonderful stories are told of a new type-setting machine in Berlin called the "Electrotype." Its operations are described as automatic, the copy being fed into it in the form of a specially prepared slip of paper. A small electrotype motor drives each machine, which is said to turn out 20,000 ems per hour—about 10 times as much as an ordinary compositor will set. One boy can attend to several of these machines at once. It is said, "not only does the strip operate the keys of the machine, but the spacing is done automatically." This is a little strong. We can imagine mechanical contrivances doing a great many things, but how spacing between the words can be done automatically is more than our limited capacity for such operations enables us to imagine. At present we confess that we simply disbelieve the assertion altogether, and if an insupportable assertion like this is made about one part of the machine, it justifies us in taking a liberal discount off those laudatory comments upon it which have now set out on that long journey generally described as "going the rounds of the Press."

The Telephotograph.—The telephotograph is the name of a new Swedish invention, which claims to do for the eye something like what the telephone does for the ear. It is based upon the peculiarity of selenium, that its resistance to the transmission of electricity to a great extent depends upon the strength of the light to which it is exposed. The construction of the telephotograph is simple enough. A fine point of selenium is made to move in a plane by a mechanical arrangement in such a manner that it, moving within a limited compass of this plane repeatedly forwards and backwards, describes a spiral consisting of very close windings. An electric current passes through the selenium point, and the power of this current will vary according to the light to which the point at any given moment is exposed. The receiver is constructed in a similar manner to the above, except that a very susceptible incandescent light has been substituted for the selenium point. The intensity of this light varies in harmony with the light to which the selenium point is exposed. When the incandescent light is made to move in a similar manner to the movements of the selenium point, it will produce lights and shadows on the plane similar to those through which the selenium point passes in its plane. The despatching apparatus is enclosed in a case, something like a photographic camera, fitted with an objective, which can be so adjusted that the picture of the subject to be telphotographed is formed in the movement plane of the selenium point. The lights and shadows produced by the incandescent light of the receiving apparatus will then produce a picture identical with the one at the despatching station. This picture can be made visible in various manners, either through photography or by being directly looked at through some magnifier, or in a similar manner to the one used in a magic lantern. The rapidity of the movements of the selenium point through any one point of the picture must not allow of a greater interval than about one-eighth of a second, so that the corresponding impressions upon the eye of the beholder form a continuous complete picture.

Queen Anne is Dead.—The *Daily News*, which each day gives a couple of columns or so of matter much of which has an antediluvian odour about it, discovered on Friday last that "*A* French electrician, M. d'Arsonval, has succeeded in accurately measuring the electric energy of the torpedo fish." Some people are unaware that the *Daily News* is a daily comic paper. But it is. This item is published under the ironical heading of "This Morning's News.' Good morning, and never mind the soap. Moreover, the paragraph, to give it additional importance, is attributed to "Our Paris Correspondent." Possibly, the belatedness of the news may be due to the callousness of a lady journalist to anything but new dresses, but, in any case, the *Daily*

Digitized by Google

News, if their sub-editors looked about in the proper channels, would have found all the details of M. d'Arsonval's experiments in the *Electrical Engineer* of August 9, page 145, which, though not headed "This Morning's News," antedates the Bouverie-street paper by a week. Equally up to date is the *Echo* of Saturday last, which lays forth upon the subject of the North Sea-Baltic Canal lighting. It then found out that the canal "will be amply lighted by electricity." We gave the full account of the method by which it had been lighted in our issue of June 21. Then we are told that the lighting is to be effected by one 16-c.p. lamp on each side about 300ft. apart. The fact is that, by the official information which we received, the lamps are of 25 c.p. and that the distances between the lamps average between 600ft. and 700ft. But possibly the *Echo* can only be depended upon when recording the "charitable" exploits of Mr. Passmore Edwards. The current issue of *Pearson's Weekly* states that "in Germany electric cars have been prohibited on the road which passes the Imperial Technical Institute. Experiments have shown that the current for the track affected the delicate instruments in the building, making scientific observations and experiments impossible." The proper particulars of the incident referred to were given in a note in this journal on August 2. Then *Fun* says that "one of the ideas for *next year's exhibition* at Amsterdam is an electrical restaurant. People are to feed electrically on electrically-cooked viands. After that, they will probably want to be electrocuted." The Amsterdam exhibition referred to is this year's, which was opened months ago.

Self-Propelled Road Carriages.—In connection with the offer of the *Engineer* of 1,000 guineas in competition prizes for self-propelled road carriages, the editors believe that the construction of such carriages may very well constitute a new branch of manufacture at least as important as that of cycles, which in a very few years has attained to enormous proportions. But they state that it is obvious that unless the use of vehicles propelled by steam, oil, gas, or electricity is sanctioned by the Legislature, no progress can be made in this direction. It will be remembered that an alteration in the existing Highways (Locomotives) Act was prepared and met with favour in the late Parliament, and would probably have become law but for the dissolution. It is most desirable that the existence of a demand for such a change should be brought to the notice of the new Government, and to that end they have prepared the subjoined memorial. They point out that energetic action at the present moment will be of far more value than at a subsequent period when Parliament becomes engrossed with matters which, however important for the nation in general, have scant interest by comparison for engineers. The memorial runs as follows: "Towards the close of the last Parliament the late Government introduced a Bill for the repeal of existing statutes, so far as they operate to prevent the use of light vehicles propelled by steam, or other motive power not employed in traction. The Bill was read a first time, but by reason of the dissolution did not proceed further. Your memorialists believe that the time has now come when such a measure should be passed into law. They point to France for an example of the use that is made of motive power upon roads, and they respectfully urge that this country should not be in a less favourable position. The fact that there is no opening for the use of light road carriages in this country by reason of restrictive statutes operates to prevent the development of a trade in such articles in competition with other countries where such restrictions do not exist. The passing of such a measure as that introduced during the last session of Parliament would lead to a large development of trade, and to the benefit of a large section of the operative classes of the country."

Personal.—Mr. Alfred Dickinson, recently manager of the South Staffordshire Tramways Company, has been the recipient of a handsome tribute to his worth. A large number of employés of the company assembled at the Darlaston depôt to make him a presentation. Mr. Dickinson is still engineer to the Electric Construction Company for the electric line, and is at present chief engineer to the Birmingham Central Tramways Company. Having accepted the Birmingham appointment, he has resigned his office at Darlaston. The presentation was made in the open air by Mr. W. H. Duignan (Walsall), who said that the company had assembled to show their personal respect and affection for Mr. Dickinson during the period he had held the office of manager of the South Staffordshire Tramways Company. Mr. Dickinson had discharged his duties for the past 12 years in such a manner as to earn the respect and affection of all who came in contact with him. They hoped he would have success in his new appointment, and would have greater happiness and comfort than in the past. He then handed to Mr. Dickinson an illuminated address, expressing regret at his severance from the company after 12 years of faithful and valuable service, recording high appreciation of his ability and general courtesy, and asking his acceptance of a drawing-room cabinet, desk, chair, and gold pencil-case as tokens of regret and esteem. Mr. Dickinson, in reply on behalf of his wife and himself, thanked those present for their expressions of goodwill. He said that in 1885—the year he took charge as general manager—the South Staffordshire Company's cars ran 442,634 miles, carried 3,438,819 passengers, while the earnings were £17,650. Last year the number of miles covered was 624,747, passengers carried 4,839,402, and earnings £30,984. So that in his management—and he gave it simply as a record—when he took charge, the earnings of the company were £17,650 per annum, and when he left it they were £30,984 per annum. He hoped there was a brighter future before the company. He was sure there was if an improved method of traction could be introduced.—Mr. E. C. C. Baly, University College, London, has been awarded honourable mention by the committee appointed by the Smithsonian Institution to award the Hodgkins Fund prizes for his paper, "The Decomposition of the Two Constituents of the Atmosphere by means of the Passage of the Electric Spark."

A Disclaimer.—Mr. Sporting Notions, of the *Referee*, on Sunday last wrote as follows: "If only the *Referee* were an illustrated paper! I mean, of course, 'illustrated' in the artistic acceptance. We are all modestly conscious that each contributor not only illustrates, but illuminates it—but that by the way. With liberty to insert a cut culled from the *Electrical Engineer* (whose editor I beg to thank for kind attentions), we could show how battles pugilistic are to be fought and won in the near future. At least how they will be fought and won if pugs adopt a patent for which one Donovan is to be held responsible. Let Mr. Donovan—Mr. Joseph Donovan, of Chicago—explain the fixings for himself, also for the world's benefit. I deeply regret inability to reproduce the cut depicting a gladiator armed in this apparatus and nothing much else. He has an electric stud on his nose and similar automatic registering devices on or about the jaw bones. The 'darby,' as fixed up with patent knobs, is marked out in sections, numbered or lettered, as targets are at rifle meetings. The authorities do not do this, you know, but enterprising newspaper agencies do, so that you can practically send by wire a plan of a target showing the hits. Says Mr. D.: 'It is well known that sparring or

Digitized by Google

boxing is one of the most health-giving exercises in the whole range of athletics, developing endurance, stability of physique, a quickness of eyesight and action, and tending to bring out in its finest and quickest form every muscle of the body. Unfortunately, however, with all these good qualities there is a roughness and brutality with it, which has thrown it almost entirely outside the pale of legitimate athletics, and to eliminate these rough and objectionable features entirely to those practising boxing by padding over all the vulnerable points above the belt and providing each and all of these points with a registering device, so that all blows shall be rung up and registered automatically, thus reducing boxing to a simple test of quickness and endurance, and nothing more, is the principal object of my invention.' Bully for you, Donovan, my brave, inventive genius! We want chaps with brains like you to go a bit further and save a whole pile of trouble. Carry this great invention only to another step or two and we can reduce boxing to a sort of kriegspiel, with or without the mittens. Only to think of being able to sit at home and get all details of a big fight served up hot and put on the tape as one might a chess problem." In order to avoid errors, we may mention that we have paid no attentions, kind or otherwise, to Mr. Sporting Notions, and that we have never heard from Mr. Joseph Donovan, of Chicago.

The Patent Office and its Publications.—Mr. W. Fairburn Hart writes: "In the 'Twelfth Report of the Comptroller-General of Patents, Designs, and Trade Marks' for the year 1894, recently published by order of Parliament, special attention is directed to the fact that the largest increase in patent applications from foreign countries is from Belgium, Germany, and Sweden, 'the number from France (the report states) having remained, curiously, stationary during the past 10 years,' whilst 'the applications from the United States of America, which reached the number of 2,597 in 1890, have fallen off since that date, and amounted to 2,017 in 1894.' In view of the expected revival of trade, it is interesting to turn to one of the appendices of the same report and find how liberal our officials have been in donations of complete sets of the Patent Office publications to foreign Governments. Each set, it was officially announced in 1885, consisted of 4,040 volumes, and cost for printing and paper £4,270, complete sets having been presented to foreign countries as follows: Germany, eight sets; Belgium, two sets; and Sweden, one set; besides which abridgments of the specifications are sent to two additional places in the German Empire, and the 'Illustrated Official Journal of Patents' to another two places in Germany, and one in Belgium. The United States of America has received 12 complete sets of publications, besides 14 sets of abridgments of specifications and four copies of the 'Illustrated Official Journal of Patents,' for which since 1893 at the least 10 sets of United States specifications have been received in return, and these, the report states, may be consulted in the free public library of the Patent Office, London, and at the public libraries in Birmingham, Bristol, Cardiff, Dundee, Glasgow, Hull, Leeds, Manchester, and Sheffield. The Government of the United States of America is apparently the only country which sends more than one set of their publications in exchange for those received from this country, except France and Belgium, which formerly sent, if not at present, an additional set of publications relating to their specifications to the British Museum. If it is so important to obtain something like a fair exchange of patent publications from a country in which the applications received here are shown to be decreasing since 1890, why should not more than one set be obtained from Germany, and which set is only to be seen at the Patent Office Library in London? With the constant references that are made to keen German competition in all branches of trade, and in view of the fact that a British patent may be found to be invalid if a foreign specification has been deposited, so as to be available to the public, in a library in the United Kingdom, has not the time arrived when efforts should be made for obtaining an equivalent return of publications from the German Patent Office particularly, as well as from other countries, and when obtained to have them distributed to the public libraries, as is done with those received from America?"

The Counter E.M.F. in the Electric Arc.—Mr. W. H. Freedman, in the course of a long article on this subject in *Electric Power*, comes to the following conclusions: (1) There is a counter E.M.F. present in an electric arc depending simply upon the material of the electrodes and the temperature of volatilisation of that material, and this counter E.M.F. has a constant definite value for that material. For as far as the vaporisation of the material of the electrode is concerned this represents a certain amount of energy, and must be supplied by the electrical energy of the circuit. Therefore at this point in the circuit there must be a sudden fall in potential, such that this fall of potential multiplied by the current represents the energy necessary to vaporise the electrode. Such a counter E.M.F. must remain constant as long as the temperature of volatilisation of the electrode remains constant. (2) On account of the different temperatures, there must be a thermo-electric effect. That is, there is a thermo-electric couple of the material of the electrode and of its vapour, whose junction is at a much higher temperature than the rest of the circuit. The counter E.M.F. due to this phenomenon must depend upon the difference of temperature between the electrodes. Consequently it must increase with the length of the arc, as the temperature of the negative electrode rises. (3) It is fair to assume that two amperes of current will tear off twice as many molecules in the same length of time from the positive electrode as one ampere, in strict analogy to electro-deposition. If the matter of matter be doubled, the resistance is most likely halved, so that C R would remain a constant quantity. This would be so provided the temperature remained constant; but since the temperature rises with increase of current, and the resistance of flames decreases with increase of temperature, C R must actually decrease with increase of current. Now the decrease of voltage with the increase of current for a given fixed distance can be explained. By Ohm's law $C = \frac{E}{R}$. The effective E.M.F. in the present case is $E = V - x - y$; V = difference of potential between the electrodes; x = constant counter E.M.F.; y = variable counter E.M.F. Solving, we get $V = x + y + CR$. Taking any fixed distance, we see that V will increase as the current increases, since x remains constant, and both y and C R decrease in value. This, then, is the complete formula for the difference of potential between the electrodes, in which x = the constant counter E.M.F. depending upon the material of the electrodes and its temperature of volatilisation, y = the counter E.M.F. due to the thermo-electric effect being a function of the material of the electrodes and the difference of the temperatures; the higher temperature being that of volatilisation of the electrode, and the lower depending upon the material and size of the electrode, the current, and length of the arc. C = the current strength; R = the ohmic resistance of the arc depending upon the material of the electrodes, the length of the arc, and the temperature or the current. For any given material of electrodes

analytically expressed in terms of length and current, $V = x + f(l_1 C) + C f^1(l_1 C)$; or in terms of temperature and currents, $V = x + f(t_2, t_1) + C f^1(t_2, t_1)$.

Refuse Disposal and Electric Lighting.—In continuation of this subject, a paper on which was read by Mr. Manville, M.I.E.E., at the recent Hull Congress of the British Institute of Public Health, and reproduced in our last issue, it will be interesting to note the following extract from the remarks made by Mr. S. J. Beaman, of Warrington, at the same congress. Mr. Beaman said: I venture to presume that most, if not all, present are of opinion that the most common-sense and rational manner of the disposal of such a conglomerated mass of offensive material as town's refuse is by burning it. But in this utilitarian age the mere process of burning it simply to get rid of it will not long be tolerated or countenanced, but it will be requisitioned to serve some public and beneficial purpose other than merely producing a clinker for concrete, or for the clinker being ground into mortar when mixed with lime. In this electric lighting age the steam generated by the burning of the refuse can be most advantageously utilised. Hitherto due justice has not been done to the destructor furnace as a steam generator; it has been looked upon as of secondary importance, simply as an auxiliary, and as only capable in some small degree of lessening the consumption of coal. This is scarcely a matter for surprise taking into consideration the very meagre results obtained. These actual results vary very considerably; some authorities give them as low as 3 i.h.p. per cell and some as high as 15 i.h.p. per cell, calculated upon the basis of 20lb. of steam per hour as equal to 1 i.h.p. If we take the higher estimate, 15 i.h.p. per cell, I think you will agree with me that even this is far from satisfactory when compared with others. I am not going to enter upon a dissertation of the calorific value of town's refuse, because it differs very much in its composition in different localities and even in the same locality at different seasons of the year. Mr. William Warner, of Nottingham, in his paper which he read two years ago, "On the Disposal of Refuse," after citing the amount of steam produced per cell at several towns, says: "It will be seen from these figures that we cannot look forward to a large amount of power for electric lighting, and it is even questionable whether the power generated could be usefully adopted for that purpose." The question that naturally suggests itself is, Can destructor furnaces burning town's refuse generate sufficient steam power (without at the same time impairing their hygienic properties as destructors) as to become the most important factor in the generation of electrical energy? I unhesitatingly answer it in the affirmative. Mr. G. Watson, of Leeds, whose paper and figures have been quoted times without number by sanitary engineers who have written upon this subject, calculates upon the analysis of the products of combustion of Mr. Horsfall's furnace, and upon the specific heats and weights of the component gases, that 1,192lb. of water can be converted into steam at 70lb. pressure by the combustion of ¼ ton of refuse in one cell in one hour. Supposing an engine to consume 20lb. of steam per indicated horse-power per hour, we have theoretically from one cell in this system 59·6 i.h.p. all the time it is working. But Mr. Watson significantly adds, "So much for the theory." This theoretical 59·6 i.h.p. per cell when reduced to the practical amounts to only 15 i.h.p. per cell, which is greatly in excess of the steam produced per cell by other systems.

Road Traction.—The eighth annual meeting of the Institute of British Carriage-Builders was opened at Tunbridge Wells on Tuesday, when Mr. John Philipson, of Newcastle, the president, delivered an address, in the course of which he said: "The fact that a Bill has recently been introduced in the House of Commons to amend the law with respect to the use of locomotives on highways, is one that no coachmaker can regard with indifference. Its object is to exempt carriages, propelled by other than horse power, from the regulations of the Locomotives Act in cases where they are not used for traction purposes. Now, the Locomotive Act was passed mainly with the object of applying to engines used for traction purposes, and it was totally inapplicable to the light horseless carriages which are used in Paris and other parts of France. By the law of this country, the road engine cannot proceed at a greater speed than four miles per hour in the country, and two miles per hour in the town, and the object of the new Bill is to remove the legal obstacle as to speed in order that we may try those light self-propelled carriages which are used in France, where they are very correctly called "automobiles." It is not to be believed that our country, which builds locomotives as excellent as any that are made, and which for a long time led the world in their production, can any longer refrain from following the lead of its neighbours in experiments which have yielded such valuable results. The opinion has recently been expressed in the *Standard* that if once the trammels are taken off this method of locomotion in the United Kingdom, the development that will follow will assuredly grow to extraordinary proportions, and I am bound to confess that I concur in this view. It may become a reality which we, as coachmakers, will have to face in the near future. I am not pessimist enough to believe that carriage manufacturers, as we now understand it, will suffer to any great extent, or that the production of harness will be less. The number of horses and carriages did not decrease as was predicted when the locomotive displaced the coach. It is possible to create a demand and a new industry without injuriously affecting those already in existence. We have seen this in the marvellous extension of cycling. But if horseless carriages come into general use in this country, it will be our duty, as assuredly it will be to our interest, to take care that their manufacture, in so far as concerns everything but the motor, is the work of the carriage manufacturer. In the interests of our trade we must watch the improvements which are being constantly effected in machinery, and particularly in the application of electricity. To a limited extent we have availed ourselves of its advantages in the lighting of carriages, and I hope that we may soon be enabled to adopt the electric welding process described by Mr. Manville last year. It is a powerful auxiliary within the reach, if not of the coachmaker, at any rate of those who supply him with some of his ironwork. I need not dwell upon the importance of what is termed the efficient union of the materials of which a structure is composed. In the case of such parts of a carriage ironwork as the axles, the tires, and the bodyplates, the necessity for efficient union is imperative. There is always a doubt about a weld, no matter how good it may appear and how well it may bear certain tests. An imperfect weld may be the result of several causes—too little or too much heat, insufficient hammering, the presence of vitrified oxide, or of dirt. It is most frequently the latter. In the case of electric welding, the condition of purity is fulfilled. We obtain an equal temperature in the pieces to be joined, as the inner parts of the metal may be brought up to be fused, and the operation is not only perfectly performed, but it is done much quicker than by the older methods. The method offers great advantages to the manufacturer of coach axles, and its use would be a guarantee to his customers of the reliability of his productions."

THE POTENTIOMETER AND ITS USES.

BY ELLIS H. CRAPPER, A.I.E.E.

(Concluded from page 147.)

§ 5. *Measuring Higher E.M.F.'s.*—The previous example is a very convenient method for the determination or comparison of E.M.F.'s of single cells; but since a D.P. of only two volts is maintained between the ends of the potentiometer wire, it is evident that some modification is necessary to measure higher E.M.F.'s than two volts by comparison with one standard Clark cell. It will be apparent from a glance at the figure below that the same principle upon which the potentiometer itself depends, is applied in the additional piece of apparatus required, which is sometimes called a *volt-box* and sometimes a *multiplying resistance.* This is marked V B in Fig. 6, and, in fact, is nothing more than a divided resistance, arranged in sections so that the resistances of the different sections are definite fractions of the whole resistance between x and z. By this means it is clear that the D.P. between the ends of one of the smaller sections—as $x y$, say—is a definite fraction of the fall of potential along the resistance $x z$. The volt-box is usually arranged so as to allow any convenient fraction of the total fall of potential along $x z$—such as $\frac{1}{10}$, $\frac{1}{100}$, or $\frac{1}{1000}$—being used as may be desired. The first $\frac{1}{10}$, or, as we shall express it, 10 : 1 arrangement—*i.e.*, the ratio of the total resistance of $x z$ to the resistance of the smallest section—is suitable for the measurement of the E.M.F.'s of batteries, whilst the $\frac{1}{100}$ and $\frac{1}{1000}$ (or the 100 : 1 and 1,000 : 1) arrangements are suitable for higher E.M.F.'s; so that we are enabled to compare the E.M.F.'s of several hundred volts with the E.M.F. of a single-standard Clark cell.

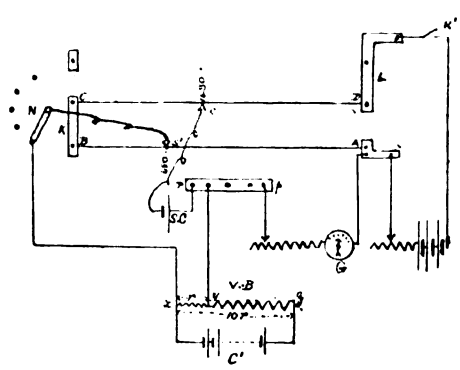

FIG. 6.

Fig. 6 shows a diagrammatic sketch of the complete arrangement suitable for the determination of the E.M.F. of a battery, and will of itself, from what has already been said, explain the theory of the method adopted. C^1 is the battery of E.M.F., E^1 volts which is required. $x z$ is the volt-box, set up with the 10 : 1 arrangement.

As before, the slider, s, is placed at the division corresponding to the E.M.F. of the standard cell, S C, for the temperature of the room, as given in the table previously, and a D.P. of two volts maintained between the terminals, A D, of the potentiometer wire. In the case shown the E.M.F. of the standard is 1·43, since the slider, s, is at the division 1,430, and the slider s^1 is placed at 680, which gives 0·68 volt as the D.P. between the points x and y. But the E.M.F. of the battery, C^1—*i.e.*, the D.P. between x and z—is 10 times the D.P. between x and y, consequently, the E.M.F., E^1, is $10 \times 0{\cdot}68$ or 6·8 volts. It will be noticed that with the arrangement as shown, any E.M.F. up to 20 volts may be measured; also by arranging the volt-box to give 100 : 1, up to 200 volts may be measured, and so on.

§ 6. *Standardisation of Voltmeters.*—To check the readings of a voltmeter, the same method is employed, but it is necessary to point out that arrangements must be made so as to permit of various voltages—so as to include the whole range of the readings of the voltmeter under test—being put between the terminals of the voltmeter, as required. This is done as follows: the voltmeter is connected across the terminals, $x z$, of the volt box, to which are also connected the terminals, $u v$, of an incandescent lamp, the voltage of which should be the same as the maximum reading of the voltmeter. The incandescent lamp forms part of a circuit supplied with electricity from a dynamo or other source giving a constant E.M.F., so that the E.M.F. at the terminals, $u v$, of the lamp may be made equal to the maximum voltage the voltmeter will indicate. The D.P. at the terminals of the lamp may be varied by moving the slider, s^4, along a variable resistance, $v w$, placed in series with the lamp and the source. As shown in Fig. 7, this variable resistance, or any part of it, may or may not be included in the lamp circuit as desired, by moving the slider, s^4.

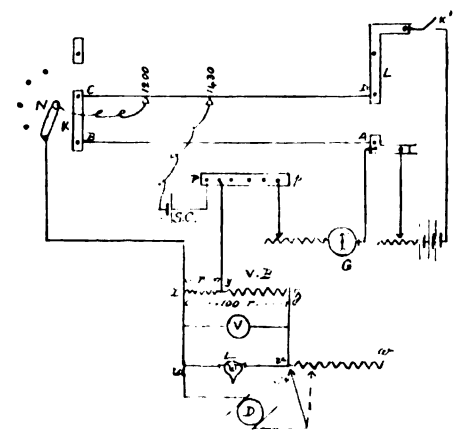

FIG. 7.

The supposed calibration of a voltmeter to read between 40 and 120 volts will illustrate the method of procedure. The volt-box is arranged to give 100 : 1, and a 120-volt lamp is inserted between u and v. The variable resistance, $v w$, in series with the lamp, is arranged so that the D.P. between the lamp terminals may decrease by five volts for each movement of the slider s^4. For instance, when the variable resistance, $v w$, is cut down, as shown, the D.P. at the lamp terminals will be 120 volts, the dynamo or other source giving a constant E.M.F. of 120 volts. When the circuits are properly balanced, the slider s^1 will be placed at division 1,200 on the potentiometer, since the D.P. between x and y is $\frac{1}{100}$ of the D.P. between the terminals, $x z$, which is the same as the D.P. at the terminals of the voltmeter. And 1,200 on the potentiometer gives 1·2 volts between x and y, consequently the voltmeter should read $1{\cdot}2 \times 100$ or 120 volts. It must be remembered that the accuracy of the measurements depend upon the exact adjustment of the potentiometer and the standard cell when setting the instrument up, and repeated readings should be taken with slider S_1 when only the standard cell is in circuit. When the first section of $v w$ is introduced, the reading will be 115 volts, and so on. From the potentiometer readings we, of course, get the various voltages at the terminals of

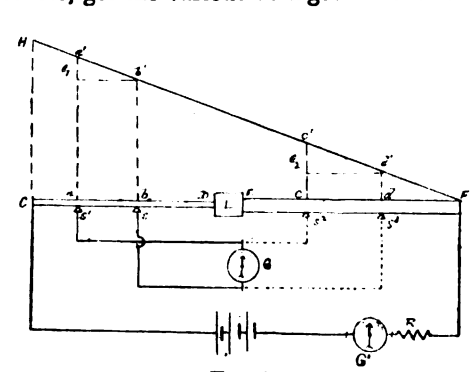

FIG. 8.

the lamp, and consequently the same voltages at the terminals of the voltmeter, and by noting the corresponding readings, a curve may be drawn indicating such errors as may exist. If a suitable incandescent lamp is not available, an equivalent resistance may be inserted between u and v.

§ 7. *Resistance and Conductivity of Wires.*—Advantage is also taken of the fact that the fall of potential between two points in a wire is proportional to the resistance between the two points, to compare resistances and to

Digitized by Google

determine the conductivity of wires. As is probably well known, one of the most exact and satisfactory methods of measuring very small resistances is by means of the fall of potential along a wire. The theory of the method is very simple, and will be readily grasped from Fig. 8. In the figure, C D and E F are two wires stretched over scales between the terminals C D and E F, D and E being connected by the thick copper piece, L. If one of the wires, C D say, which we shall call the standard wire, be made of pure copper, and the lengths of the wires denote their resistances, we can at once determine the conductivity of the other, E F, in terms of that of pure copper. If a battery of constant E.M.F. be connected to C and F, then the ordinate, C H, denotes the D.P. between the terminals C and F, and there will be a gradual fall of potential from C to F; and since, as we have already seen, the slope of the potential, H F, is a straight line, it is an easy matter to get the value of the ratio of the D.P.'s between any two sets of points, as, for instance, between the points a and b and c and d. The potential at a is denoted by the length of the ordinate $a\,a^1$, and at b by $b\,b^1$—that is, the D.P. between a and b is $(a\,a^1 - b\,b^1)$, which we will denote by e_1; similarly e_2 denotes $(c\,c^1 - d\,d^1)$ the D.P. between c and d. In practice, to get measures of e_1 and e_2, we have simply to make contact with the wire at a and b simultaneously with the sliders, s^1 and s, when we shall get a deflection, D^1, with the galvanometer, G, which is proportional to e_1; similarly, sliders s^2 and s^3 give a deflection, D^2, proportional to e_2 by making contact at c and d simultaneously. Consequently we may write—

$$\frac{e_1}{e_2} = \frac{a\,b}{c\,d} = \frac{D^1}{D^2}.$$

If we let

d_1 = deflection per unit length of standard wire $= \dfrac{D^1}{\text{cms. in } a\,b}$;

d_2 = " " " wire to be tested $= \dfrac{D^2}{\text{cms. in } c\,d}$;

r_1 = resistance of standard wire, l_1 cms. long;

r_2 = " wire, l_2 cms. long;

c_1 = conductivity of standard wire;

c_2 = " wire;

s_1 = area of cross-section of standard wire;

s_2 = " " " wire.

Then, since $R = \dfrac{\sigma\,l}{s} = \dfrac{l}{c\,.\,s}$, the general formula for resistance, in which σ is specific resistance and c specific conductivity, we may write the following equations:

$r_1 = l_1 / c_1 s_1$, and $r_2 = l_2 / c_2 s_2$; but $e_1 = C\,r_1$, and $e_2 = C\,r_2$. Therefore, $e_1 = C\,r_1 = C\,l_1 / c_1\,s_1$, and $e_2 = C\,l_2 / c_2\,s_2$. From which we get

$$\frac{e_1}{e_2} = \frac{r_1}{r_2} = \frac{l_1\,c_2\,s_2}{l_2\,c_1\,s_1} = \frac{D^1}{D^2} \quad . \quad . \quad . \quad \text{(III.)}$$

Equation III. is simplified if l_1 and l_2 be taken as unit length, and becomes

$$\frac{e_1}{e_2} = \frac{c_2\,s_2}{c_1\,s_1} = \frac{d_1}{d_2} \quad . \quad . \quad . \quad . \quad \text{(IV.)}$$

therefore

$$c_2 = c_1 \times \frac{d_1}{d_2} \times \frac{s_1}{s_2}. \quad . \quad . \quad . \quad \text{(V.)}$$

If $s_1 = s_2$, then $c_2 = c_1 \times \dfrac{d_1}{d_2}$, c_1, the conductivity of the standard wire, is expressed as a number, that of pure copper being taken as the standard of reference and denoted by 100. The method of applying these principles is shown in Fig. 9, in which the letters correspond with those in Fig. 8.

In the potentiometer shown in Fig. 5, the standard wire, C D, is made of platinoid ·355mm. in diameter, consequently a preliminary test is necessary to determine its conductivity with reference to pure copper. This is done by connecting a pure copper wire between E and F, which, for the time being, is the standard wire, its conductivity being 100. From a large number of tests, the conductivity of the platinoid wire of this potentiometer has been found to be 4·75; this number is marked on the instrument for future use, and need not be determined each time the instrument is used. It will be noticed in Figs. 8 and 9 that two galvanometers are shown connected up, one, G, a high-resistance galvanometer, from which the readings are taken, whilst the other, G^1, is used simply to check the constancy of the current during the test. To determine d_1 and d_2, the slider s^1 is fixed at any convenient position, a in C D, and the slider s at b, so that the D.P. between a and b gives a convenient deflection, D^1. Dividing this by the number of centimetres between a and b we get d_1.

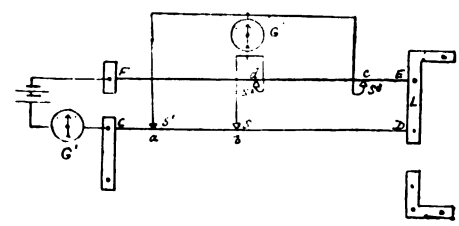

Fig. 9.

In a similar manner we get d_2 by means of sliders s^2 and s^3. Then

$$c_2 = c_1 \times \frac{d_1}{d_2} \times \frac{s_1}{s_2} = 4{\cdot}75 \times \frac{d_1}{d_2} \times \frac{s_1}{s_2}.$$

The particulars and results of an actual investigation respecting the conductivities of two samples of German silver and brass wires will now be given as examples. The diameter of the standard platinoid wire is ·355mm.

(I.) German silver wire, ·75mm. diameter, stretched between E and F.

D_1 was 328 when $a\,b = 10$cm. $\therefore\ d_1 = 328/19$;

D_2 was 95 when $c\,d = 39$cm. $\therefore\ d_2 = 95/39$;

since $s = \dfrac{\pi}{4}(\text{diam.})^2 \therefore s_1 = \dfrac{\pi}{4}(\cdot355)^2$, and $s_2 = \dfrac{\pi}{4}(\cdot75)^2$.

Substituting these values we get

$$C_2 = 4{\cdot}75 \times \frac{328}{19} \times \frac{39}{95} \times \frac{\pi}{4} \times \frac{\cdot355 \times \cdot355}{\cdot75 \times \cdot75} \times \frac{4}{\pi}$$

$$= 7{\cdot}54$$

II.—Brass wire, ·355mm. diameter

D_1 was 345 for 20cm. $\therefore\ d_1 = 345/20$

D_2 was 240 for 45cm. $\therefore\ d_2 = 240/45$

and $S_1 = S_2$,

$$\therefore\ C_2 = 4{\cdot}7 \times \frac{345}{20} \times \frac{45}{240}$$

$$= 15{\cdot}36.$$

As the connections for the determination of specific resistance and the measurement of very small resistances, shown in Fig. 10, explain themselves, it will be sufficient if we briefly describe the standard resistance, S R, and the switch, K^2. The standard resistance consists simply of ten

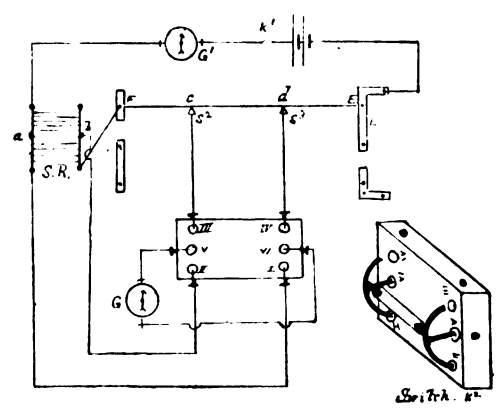

Fig. 10.

0·1 ohm resistance coils—accurately determined—connected in multiple arc, so that we have at hand a 0·01 ohm standard coil, which, within considerable limits, will not be heated by large currents passing through it. When we know the D.P. existing at its terminals, we can determine the resistance between any other two points by means of the D.P. between them, provided the same current passes through both. The switch is simply a Pohl's commutator modified, and consists of an ebonite base with six mercury

Digitized by Google

cups, I., II., III., IV., V., and VI., each connected to a terminal. The high-resistance galvanometer is connected to cups V. and VI., in which are placed the two metal uprights of the switch, which is hinged so that contact may be made quite readily with either pair of cups, I. and II., or III. and IV. By means of this switch the galvanometer, G, is placed in circuit with the points a and b, or with c and d. When G is in circuit with a and b, the deflection D^1 measures e_1, the D.P. between a and b, and when III. and IV. are in circuit with G the deflection, D^2, measures e_2, the D.P. between c and d. From a consideration of the principles it is obvious that several methods may be adopted in making these tests. We may find D^2 for a definite length between c and d, and calculate the value of r_2, from $r_2 = r_1 \times D^2 / D^1$, r_1 being ·01 ohm, since,

$$r_2 / r_1 = e_2 / e_1 = D^2 / D^1;$$

or we may vary the distance between s^2 and s^3 until $D^2 = D^1$, or, in other words, find a length of the wire which has the same resistance as the standard. An actual example of a determination of the specific resistance of an aluminium wire ·089cm. in diameter, will now be given as a worked example.

D^1 was 120 when the standard coil was in circuit with G; D^2 was 200 when 35cm. of the aluminium was in circuit.

Then, since $r_2/r_1 = e_2/e_1 = D^2/D^1$, the resistance of 35cms. of aluminium was

$$r_2 = \cdot 01 \times \frac{200}{120} = \frac{1}{60} \text{ ohm.}$$

The specific resistance is calculated from the formula $R = \frac{\sigma l}{s}$, where σ = specific resistance, l = length in centimetres, and s = cross-sectional area in square centimetres; $s = 00621$ square centimetres.

$$\frac{1}{60} = \frac{\sigma \times 35}{\cdot 00621}, \text{ and } \sigma = \frac{\cdot 00621}{60 \times 35} = \cdot 00000296 \text{ ohm.}$$

$\therefore \sigma = 2{\cdot}96$ microhms.

§ 8. *Measurements of Currents and Calibration of Ammeters.* We shall in this test simply point out one or two details, as Fig. 11 explains itself. By means of slider s^1 the D.P.

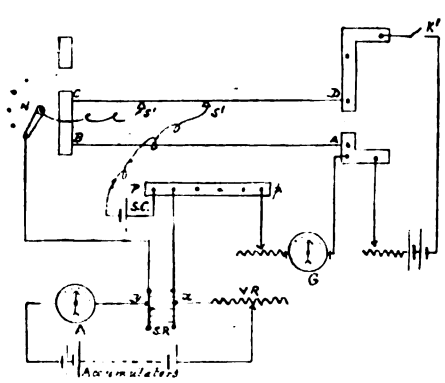

FIG. 11.

between x and y may be measured when a steady current—preferably from accumulators—is sent through x y, a known resistance, the magnitude of which is suitable for the current flowing. In all cases the resistance of x y is small, so that the D.P. between x and y does not exceed two volts. Then, since $\frac{\text{D.P.}}{\text{resistance}}$ = current, the current is easily determined. If an ammeter is to be checked, it is placed in series with x y, as at A, and the current is varied by means of the variable resistance, V R.

MUNICIPAL ELECTRICITY.*

BY JAMES PERRY.

For six years, as part owner and engineer, the writer has been connected with the public and private supply of electricity in Galway, and he has thought that his views and experience in this department might have some interest to his brother municipal engineers. The counties in Great Britain have been municipalised, those of Ireland are about to be, and there appears to be a prospect of legitimate shortening of our title. Most of us as officers are entitled "surveyors." It is a good old title, honoured and ennobled by the men who have preceded us, and not to be lightly discarded; but it records our origin, and marks the gradual growth in complexity of our functions. The rapid march of civilisation during the last 100 years, the steady rise of the standard of comfort and decency, the recognition of the mutual dependence of all citizens, rich and poor, in preventing disease—appliances for street cleansing; systems of sewerage, with pumping machinery; waterworks; gasworks; tramways—necessitates that the city surveyor shall be an engineer in the widest sense. As a specialist in a department he might attain greater riches and wider fame; his part is to select and control specialists as a commander-in-chief controls the complex and highly scientific departments of a modern army. Electricity—electrical engineering if some prefer so to speak—is forced upon us, and we have got to do our duty in regard to it as we have done our duty by the other human refinements which have preceded it. Most of us are specialists in some direction as a relief and variety from the routine of official duty, and some of us are no doubt electricians as some of us are artists or musicians; but an electrical engineer is not necessarily an electrician, just as a mariner is not necessarily an astronomer. There has been for some years in the public mind a confusion between electricians and electrical engineers which would be paralleled by supposing mariners and astronomers to be the same. Astronomers have done good work for mariners, and electricians are doing good work for engineers, but a mere electrician is not an engineer, and when he undertakes an engineering job, he necessarily makes a mess of it. There has been a good deal of messing. Let us take two examples: The scientific gentleman who is mainly responsible for the "London Supply" is a man of undoubted ability, and as an electrician his reputation has scarcely suffered by the gigantic failure of that venture. The financially most successful man is probably Edison, who is by training neither an engineer nor an electrician (he is reported to have sworn in court that he did not know Ohm's law), but who appears to be endowed in a high degree with a combination of the qualities of common sense and ingenuity which makes him comparable to our own George Stephenson.

The engineer has to deal with commonplace electricity: he should in general treat it as Peter Bell did the primrose—let his cow eat it and turn it into butter. The engineer's electricity is comparable to a leather belt or steel shafting and gearing. It is not a source of power; its humble function in the telephone, telegraph, electric motor, electric lamp, is to transmit power to a distance. Pretentious youngsters and high-falutin newspaper men may talk of the age of steam to be succeeded by the age of electricity; they might as well talk of the coming age of leather belts or of steel shafting. Why should a dairy maid, whose business it is to make good butter, bring to her butter-making the botany of the plants eaten by the cows, the physiology of the cows, and the chemical composition of the butter? It would be useful for the intelligent dairymaid to know how many ounces of butter she ought to get from a gallon of milk, the temperature at which butter comes, how much water to leave in the buttor, and how she can best wash out all the remains of the milk, and she should have proper appliances to enable her to carry out the processes cleanly and properly.

The generation of electricity is purely a question of mechanical engineering. The laying of mains involves digging and paving, the wiring of houses is a kind of plumbing, the laying of an electrical tramway is a piece of ordinary tramway engineering. The electricians have a great variety of units which they have variously named and symbolised, so that it becomes more and more difficult for plain men to understand what they write, and they tend more and more to become a select half-dozen—for the whole world—who can dispute with one another in a

* A paper read before the Incorporated Association of Municipal and County Engineers at Londonderry.

Digitized by Google

language which no outsider understands. Engineers who desire to keep sane should avoid trying to comprehend the discussions in which English prepositions and conjunctions are mixed up with block letters and German text letters which in mercy to the eyes of Germans have been banished from their books) and occult phrases and names of dead persons, but it is necessary to know something of the way in which electricity is measured, and useful to know the small equation which expresses Ohm's law.

Electricity leaving a central station passing round an external circuit and returning to the station may be compared to an endless rope driven by a pulley in the station. If you conceive of a rope of this kind passing round capstans and through tight places of one kind and another, you will see that when it is made to circulate it will turn the capstans and heat the tight places. Note the rope comes in as fast as it goes out, and no faster, but it comes on to the pulley tight and leaves it slack. Let us call the speed of the rope amperes and the tightness of it volts; the speed is the same at every part (except for elastic movements which we may neglect), but the tightness varies. As many amperes return to the central station (assuming there is no transforming) as leave it, but the volts vary from point to point. Now, if we multiply the tightness or pull by the speed we have the power transmitted at any point. Volts multiplied by amperes measure power. It is of no great consequence how the units, ampere and volt, have been fixed. The volt means pressure or tightness of the rope; the ampere means speed or quantity per second; amperes and volts multiplied together are watts; and now we are in familiar ground, because 746 watts are a horse-power. When 1,000 watts run for an hour it is called a Board of Trade unit. A unit of electricity, for which we in Galway charge 3d., used in printing or bottle-washing, or 5d. used for lighting, is equal to $1\frac{1}{3}$ h.p. for one hour. This is all absolutely exact; the unit of electricity can be stated as being 2,554,155 foot-pounds. When, however, we have to compare the value of a unit of electricity for lighting purposes with that of 1,000ft. of gas, we have the elements of lamps and burners coming in in ways which allow of a considerable field for discussion between gas conservatives and electric radicals. It is fair at this time of day to accept Gordon's estimate made long ago, that one thousand of gas is equal to 10 units of electricity, which would make electricity at 3d. equal to gas at 2s. 6d.

"Amperes" in our analogy are units of speed.

"Volts" " " pull or pressure.

Volts × amperes are "watts."

746 watts are one horse-power.

1,000 watts for one hour make one unit of electricity

The engineer has also to deal with the unit of resistance called an "ohm."

If there were no resistance to the rope running there would be no difference in the tightness between where it comes on and where it leaves the driving pulley—that is, there would be no loss of volts; but there is resistance at every supporting pulley and at every capstan and every tight place, and at all these places the rope is less strained coming on than leaving: it is losing volts owing to resistance all along its course. This resistance might be called negative volts, but it is advisable to have a distinct unit for it, the "ohm."

In any continuous-current circuit the three quantities concerned expressed in these units are connected by a relation which is shown by a simple algebraic equation, and is known as Ohm's law:

$$\text{Amperes} = \frac{\text{volts}}{\text{ohms}}.$$

This relation comes into most of the electric calculations which the engineer has to make.

If we consider the resistance to the right of A and B, and that the loss of volts between A and B is due to that resistance, it will be seen that there is a further small loss from friction between the rope and the driver, and if we wish to speak of the total pull at the maximum point in the circuit, account must be taken of this friction; we speak of the difference of volts between two points on a circuit, but the E.M.F. of the circuit is different in the way illustrated above.

An endless rope driven as shown above illustrates machines or lamps worked in series in which the same current passes through them all, and there is a more or less great drop of voltage at each lamp or machine. A modification of the illustration shows lamps or machines worked in parallel. Conceive the different machines or lamps to be worked by separate bands or fine ropes which combine through the driver, up to points A and B, to act as a single rope, and at these points separate to the several machines or lamps; we must, however, modify our idea of amperes by considering not the velocity, which is supposed to be constant, but the sectional area of each separate band as representing amperes.*

Transforming.

The power of a current is measured by amperes × volts = watts; any arrangement by which for a very small loss these two factors are varied is called a transformer. Any machine by which we obtain a mechanical advantage, wheel and axle, lever, etc., is a transformer of mechanical power. With alternating currents electrical transformation is very simple; it is not so simple for continuous currents, and in this lies a great point in favour of alternating currents for certain circumstances. There are disadvantages, and we have electricians who show some partisanship both for continuous and for alternating currents. The engineer will use whichever bests suits his special conditions. A continuous-current transformer is a machine which revolves; the alternate-current transformer has no moving parts. Accumulators, which are lead plates in cells filled with sulphuric acid, besides acting as stores for energy, are also transformers. (A diagram drawn by the author showed the arrangement for a constant-current supply with accumulators. In this A represented the engine working a shunt dynamo, B the accumulators, and C the incandescent lamps.)

Continuous-current dynamos are of three kinds (neglecting peculiarities of armature, etc.):

(1) Shunt dynamos, in which the field magnets are excited by a shunt of fine wire connecting the poles of the machine.

(2) Series dynamos, in which the total current produced by the machine passes by a thick wire round the field magnets.

(3) Compound dynamos, which have both series and shunt windings on the same machine.

Shunt dynamos are used with accumulators, because whether they revolve as dynamos or as motors they revolve in the same direction; there is always more or less chance of the dynamo and engine being driven by the accumulators. Series dynamos are used for arc lamp lighting, and compound dynamos for incandescent lamp lighting without accumulators. For five years the writer has every night run arc lamps off a shunt dynamo, and he has charged accumulators with both compound and shunt dynamos. With a turbine at an inefficient speed he has also run incandescent lamps direct from a shunt dynamo without any injury, so that the above rules in some respects are flexible.

The part of a central station in which there is any complication is the accumulator portion. Accumulators if used for storing are in first cost very expensive as compared with gasholders, and if used as regulators they involve some little complexity in connections and switches. In London, accumulators should not give very much trouble where the companies who manufacture them agree to maintain them at a percentage of their first cost per annum; but in out-of-the-way places like the West of Ireland, they will give trouble till they are set free from the last restraints of the Patent Office. With proper arrangements on the premises for remaking defective plates, the maintenance of accumulators will give very little trouble. Accumulators are specially suitable for water power because they allow of the power being utilised during the whole 24 hours. There is a loss of energy in accumulators of about 25 per cent.

* If moment can be taken as amperes it will apply to both analogues.

Digitized by Google

MAINS.—THE THREE-WIRE SYSTEM.

The filament of a incandescent lamp is of such a thickness (or sectional area) that a given uumber of amperes being forced through it heats it to the required brightness (the brightness determines the life of the lamp). In two lamps A and B, suppose A to have a filament twice the length and half the sectional area of B. A will only require half the amperes, but it will need twice the volts (or pressure) to give the same candle-power as B at the same brightness. If there was no practical limit to the fineness of filaments, we could save largely in the copper of the mains by keeping the voltage up to the limit fixed by the Board of Trade as low pressure; but it appears to be desirable to have lamps of 8 c.p., and the conditions of filament appear to limit the voltage to about 110; with cheaper electricity enabling us to use a minimum lamp of 16 candles, we could double the voltage and very much increase the capacity of our mains.

By Ohm's law, volts = amperes × ohms, but the rate of work = amperes × volts;

$$\therefore \text{rate of work} = \text{amperes}^2 \times \text{ohms (in watts)}.$$

Every current in a conductor does work by heating it; this is waste, and the rate of waste is proportional to the amperes^2, so that it is seen how important it is to keep the amperes low by keeping the volts high. It is of the greatest importance to keep the mains at an equal voltage, and our copper must be proportioned to the drop we calculate for in designing the mains. Now, suppose we calculate for a drop of two volts from one end to another of a series of lamps, and suppose the amperes to be 50 and the voltage of the lamps to be 110. If we replace the ordinary lamps by others having filaments twice as long, the cross-section remaining the same, the voltage must be increased to 220, but the lamps will give twice the light and there will be no more than the two volts drop, because the amperes will not have been increased; but if we had arranged to get twice the light at the 110 voltage with the same loss, we should have had to multiply the quantity of copper by 4, so that we save three-fourths of the copper by doubling the voltage. We need not have our double filaments in one bulb, but we may place two common lamps in series between the conductors, they need not be close together, they may be in different apartments, but they must be turned on or off together. We shall get rid of this inconvenience if we run a small main connecting the middle wires of the lamps, because if the lamps are unequal on the two sides of the middle the balance of current flows up or down the wire. This is the three-wire system. The three wires need not be carried into the houses, but consumers should be balanced on the mains in the streets.

It would appear that the network of a low-pressure system should be fed from centres about three-quarters of a mile apart. The network should consist of two conductors laid down each footpath, one of them being cross-connected to form the middle wire of a three-wire system. The size of the conductors of the network should be (probably) uniform, extra business in certain localities being provided for by extra feeders. The network should be fed by mains from which no services of any kind must be taken. These feeders will vary, so that whatever the length may be they will all have the same resistance, so that the drop in volts in each feeder shall be the same. The secondary centres may all be supplied from a principal centre, accumulator transformers being used in the secondary or feeding centres. There are continuous-current motor transformers, of which we do not hear much in actual practice, but it would appear to be quite feasible to send a high-pressure current from compound dynamos arranged to give a fixed voltage at the centres, and transform it down to the low-pressure centre voltage. Two years ago we met suggestions for small step-up transformers placed in mains so as to allow of the voltage to drop two volts below normal, and at such a point transform it up four volts, but we have heard little of this device in practice. In Galway we shall probably complete our half-mile radius of low-pressure area, and deal with the outlying straggling places with alternating currents.

The enemy to be met everywhere in a continuous-current system is electrolysis. If you maintain two pieces of copper wire at different voltages, and dip them in a solution of sulphate of copper, that which is of the higher voltage will waste away and the wire of lower voltage will become thicker. If two naked copper conductors rest on porcelain or glass insulators in an underground culvert, it is almost impossible to prevent damp from making a connection with the earth. Pure water is almost an absolute non-conductor, but the word almost condemns it, because the faintest trace of hydrated oxide of copper improves its conducting power; probably its first encouragement comes from common salt, which is a universal enemy. The rate at which the "earth" becomes good is a rapidly increasing one; it results in one main being eaten through at the insulator and the other main forming an incrustation of metallic sodium at its insulator, and this incrustation may drop off, and meeting with actual wet strike a light which fires gas which may have accumulated in the culvert from gas-mains. These culverts are exceedingly expensive things to construct; there is difficulty in keeping them drained and ventilated. Water accumulates in them; they are regular traps for water, owing to the steady temperature of the ground and the varying temperature of the air. Service connections are troublesome. Various makes of continuously insulated lead-covered mains are in the market; the difficulty with them is in service connections. Where such mains are armoured, the light character of the armouring does not promise long life in damp soils. The threading of cast-iron protecting pipes on a long length of main is difficult unless the pipes are roomy. The writer has had experience with different kinds of mains. The variety of practice in this respect indicates an uncertainty which experience will by-and-by settle; we shall in the end have only one or two kinds. The writer has devised a main of his own, but as it is yet untried he had better say little about it. Leaky electric mains, besides wasting themselves away, may do some injury to gas and water pipes buried in the ground close to them. Wherever the iron pipe is at a higher voltage than the earth in contact with it, there rusting of the iron is promoted. Tramways with rail returns may do much damage in this way. For electric lighting by gas-engines, accumulators are a necessity; any kind of throb or irregular turning shows very distinctly in incandescent lamps. For some time the writer ran incandescent lights off a compound dynamo driven by a wooden water-wheel; if the wheel stood idle for a short time so that the upper part got drier, and consequently lighter, than the lower portion of the rim, the rise and fall of the heavy part of the wheel could be seen in the lights till the wheel got equally soaked with wet all round. If alternators could be satisfactorily run with gas-engines, the question of storage of electricity would be solved, because gas may be cheaply stored, and a series of gas-engines might be put into work as the load increased and put out as the load diminished; the only inconvenience in such an arrangement being that it would be necessary to have a generating plant with reserves equal to the maximum demand. Another way of meeting the varying load is to keep the engines going all the time at a steady electrolytical manufacture of some kind which might be considered a by-product of electric lighting. With the method of differential charging to consumers the writer has but little sympathy; it is a throttling kind of action. Electric men have sooner or later to face the gas men in deadly combat as suppliers of light, and they have got to do it by reducing prices and standing on a common platform of equal rates. A differential charge for power supply is legitimate; it comes into the competition with the gas men. In the few remarks made by the writer in seconding a vote of thanks to the borough surveyor of Belfast, he suggested a 3d. rate per unit. Other people have come to this 3d. unit, and the writer is now inclined to halve it as a reasonable rate in large towns. When electricity is to be had at 1½d. a unit, a 16-c.p. lamp will keep lighting for 13 hours for 1d.

With alternating currents the writer has hitherto had no practical experience, but he is contemplating using them in the near future. The beautifully steady power of turbines, with which we work in Galway, appears to suit alternator work, but the obvious applicability of accumulators as a mean of making the most of a water power decided our commencing with continuous current. When increase of

Digitized by Google

business drives us to auxiliary power, we shall no doubt run alternators at night with our turbines and charge accumulators with them in the daytime.

A new form of tramway is just now being experimented with, worked with alternating currents, and it may possibly set at rest for ever the vexed questions between overhead trollies and underground trollies, no form of trolly, good or bad, being needed for the new kind of tramway.

The public and private lighting should be all done from the same mains. In Belfast the area selected for an experiment is an early-closing shop, and it is in this respect not the best. It would be improved by adding public to private lighting. The best kind of work is public lighting, which continues during all the hours of darkness; the worst kind is that of early-closing shops, which in summer take no light at all, and in winter they all light up together for a short time. The Belfast experiment appears to be further handicapped with dear fuel; town gas burned in gas-engines and costing 2s. 3d. a thousand is a lavishly expensive fuel. Belfast is a plucky, egotistical place, and the mass of people will not long be grovelling in worship of a row of smoky chimneys in Cromac-street.

The subject is probably too large to be satisfactorily treated in a paper of this kind. The purpose of the paper, however, is not to be a treatise on the engineering applications of electricity, but to reassure municipal engineers who are kept hard at work in an already complicated routine that this new claimant of attention is no way dangerous; that he is amenable to familiar and kindly treatment. The writer, while engaged in a varied practice, has formed a strong attachment to this new professional friend, and he is desirous that he shall receive kind treatment from his brother surveyors when he knocks—as he soon shall do—loudly at their doors.

THE NEW SCIENCE OF ELECTRIC HEATING.*

BY W. S. HADAWAY, JUN.

Heat is so closely allied to an adequate shelter in warming, and to food in cooking, that we must regard it from the practical standpoint of a prime necessity, and in treating of its generation and distribution base our deductions largely on whether the owner of a particular form of heating apparatus can operate it economically, and whether the user, or party to whom the heat energy is furnished, can employ it as cheaply as other forms of heat supply, with reasonable regard for collateral advantages. A heating system, to be an advance on existing methods, must be a source of wealth to the owner and a source of economy to the user.

A system of heat and electrical generation and transmission derives its value largely from the benefits of concentrated control, like other systems of public works. We are to regard heat agents as commodities which can be economically generated, transmitted, and applied. Electricity as a heat agent is not to be regarded as a source of heat, as that expression is generally understood, but, technically, as the high-potential heat factor in a tele thermal system, where the heat secured is generated by simple resistance; or, we may employ electricity as an agent for producing available heat in operating a thermal engine by means of motors.

Of the fuel consumed under good steam-boilers at least 65 per cent. of the heat energy is available for useful work Steam in the best of steam-engines theoretically possible can only transform 25 per cent. of the boiler energy into active mechanical work, and in practice 12½ per cent. is not generally exceeded. The engine work can be very economically transformed into electrical energy, in which form, considering it as heat, transmission losses are relatively small. In good steam and electrical practice the heat engineer can secure about 10 per cent. of the fuel energy in electricity, and of the balance of the fuel energy may write off 35 per cent. as direct loss and 55 per cent as indirect loss. The indirect loss can be utilised with a properly arranged system of steam distribution over limited distances, and the combination of the electrical energy, available for heating purposes at varying temperatures, but usually above 212deg. F., and the exhaust steam, available for heating purposes at temperatures below 212deg. F., the writer has termed a multi-potential thermal system, in which electricity is employed as the high-potential heat factor and exhaust steam as the low-potential heat-factor, and in which the heat energy is available for use in a telethermal system. That is, in practice we have a system in which the ratio of high-potential heat to low-potential heat is about 1 to 5, figured from thermal units and not temperatures, and in which the total fuel efficiency is about 50 per cent.

In domestic and industrial work we find two broad classes of heat control. The first class includes operations requiring diffused heat on a large scale, as in room and water heating, or heat of low potential and large quantity. The second class includes processes where heat is used at high temperatures and in small volume, as in cooking and laundry work and in many industrial operations, or heat of high potential and small quantity. A reasonable estimate of the relative thermal units employed in each class is found, after careful investigation, to be about 5 to 1, assuming as a line of temperature demarcation 212deg. F. The average temperature differences between the two classes are not in the same ratio as the quantities with this unit, but are sufficiently great to warrant a distinction between prices for heat energy at low potentials and at high potentials. What this difference in price should be can only be conjectured, but a fair rate of charge would seem to be not far from four or five times as much for high-potential heat as low-potential heat.

A practical illustration of the multi-potential heat system may be found in the requirements of a modern apartment house in which there are several families, each with a kitchen and small laundry under the tenants' control, and with electric lights, steam heat, and hot-water supply from a common source. The house equipment would consist of boilers, engines, dynamos, etc. The incandescent lamps, ovens, grills, flat-irons, etc., would be heated by electricity. The rooms and the water for bathing and culinary purposes would be heated mostly by exhaust steam. The owner would derive practically two profits from the fuel burned—a direct revenue from heat supplied for cooking and laundry work, and an indirect revenue from utilising the secondary products of the first.

In present practice the owner equips the house with gas ranges, which are a source of direct revenue, not to himself, but to the gas company. Electric lights, hot water, and steam heat are furnished by the owner, and figured as part of the rental value. The lights load is of so brief duration that the hot water and steam heat must come from live steam for a considerable part of the day. With a somewhat larger engine and dynamo, on the plan outlined, the live steam used would be largely supplanted by exhaust steam on account of the larger load-factor, besides providing a direct revenue to the owner to pay for fuel, labour, etc. The cost to the user of the electrical energy for cooking and laundry work at four cents. per horse-power hour is not greater than gas at 1dol. per 1,000, provided all water-heating is omitted and the electrical apparatus fairly well controlled. The user or tenant secures a great number of collateral advantages, which represent the same advantages for less money or more advantages for the same money, and the owner may convert an expense into a revenue.

The illustration brings "electric heating" within our definition of an advance in heating systems, and shows a sufficient reason why the subject should receive the respectful attention of capitalists, property owners, and their architects. It also shows that the expression "electric heating" is an unfortunate one, as the problem is one for the heat engineer, in which steam and electrical engineering are elements, and in which the electricity used is the thermal equivalent of only about one-sixth the heat energy distributed and applied.

There is, to the writer's knowledge, no installation extant completely illustrating the multi-potential system of heating. The Yaryan installation of central-station hot-water heating at Toledo, O., described in *Heating and Ventilation* (February

* From the *Engineering Magazine* (New York).

Digitized by Google

15, 1895), closely approaches it, and lacks only the application of electricity for cooking and laundering in the houses heated, and this installation is especially noteworthy in using water for thermal storage and circulation in connection with the exhaust steam heat storage. In the New York *Electrical Engineer* (April 5, 1893) will be found a description of the Springfield (III.) electric light and steam distribution plant. This installation approaches the hypothetical illustration closely enough to remove all reasonable doubt as to the strict accuracy of the deductions made for the multi-potential system.

In developing electric central stations the desirability of a large load-factor is apparent. With full knowledge of the requirements in various cases, data on electric cooking and heating have been patiently and carefully collaborated. The result entirely confirms theoretical deductions as to the extent to which the station can provide at a profit the energy for cooking and heating. There is no doubt that the central station can furnish at a profit the high-potential factor in the thermal system. The question now rests as to whether the customer or householder will find a divided heat supply desirable. Of the six parts used, the electric central station can provide one-sixth, the high-temperature part, the customer himself burning coal or gas to furnish five-sixths of the heat. The electric central station can operate electrically-heated chafing dishes and pots for five o'clock teas (replacing the alcohol lamp); curling-irons; plate warmer in the pantry; laundry irons; small water-heater for nursery; bath and dressing-room warmer, etc.; and these specialties can all be made to increase revenue without adding materially to the construction account. At a five-cent rate per horse-power hour, the devices enumerated are perfectly practicable, and other specialities, like shaving-mugs, toddy-heaters, egg-boilers, hot-plates, etc., are coming into use. These are all of value as a source of revenue to the electric central station and of convenience to the users, but it must be doubted whether, with so small a percentage of residence lighting as is now connected, and with the inability to offer but a partial heat supply when connected, electric heating apparatus, in which the heat is derived from simple resistance, will entirely provide the balance in the load sought for.

To illustrate the capacity of an electric station as a heat producer, we may compare the prices charged by the New York Steam Company and the Edison Electric Illuminating Company of New York, both operating in the same district and supplying steam and electricity respectively. Using the figures given by Dr. C. E. Emery as the basis of charges for the Steam Company, we find that it furnishes heat to large consumers at 40 cents per 1,000 kals, the kal being the equivalent of 1,110 thermal units. For 40 cents, 1,110,000 heat units are supplied. Taking the Edison Company's rates, and using the 50 per cent. discount as the rate to a large user, 40 cents will purchase eight horse-power hours, or 20,518 thermal units. The ratio between the two is nearly 54 to 1; or, as a loss must be figured in the case of steam dependent upon the temperature at which the condensed water is allowed to escape, practically 50 to 1. It would be unjust to leave the figures on the mere heat equivalent of the two forms of energy, as high-potential heat energy is almost universally secured by localising a small proportion of fuel energy and allowing the rest to escape, and is consequently worth more per heat unit; but, even were we to admit as a reasonable charge five times as much for high-potential heat as for low-potential heat, the ratio is still 10 to 1, and indicates what might be accomplished could the two plants be run conjointly for a multi-potential heat supply.

Lord Kelvin, in an article on "The Economy of the Heating or Cooling of Buildings by Means of Currents of Air," published in the Glasgow *Philosophical Proceedings*, vol. iii., December, 1852, and followed by mathematical demonstrations in the *Cambridge and Dublin Mathematical Journal* for November, 1853, has made some most interesting deductions:

"In the mathematical investigation it is shown that, according to the general principles of the dynamic theory of heat, any substance may be heated 30deg. above the atmospheric temperature by means of a properly-contrived machine driven by an agent spending not more than about one thirty-fifth of the energy of the heat thus communicated, and that a corresponding machine, or the same machine worked backwards, may be employed to produce cooling effects, requiring about the same expenditure of energy in working it to cool the same substance through a similar range of temperature. When a body is heated by such means, about $\frac{34}{35}$ of the heat is drawn from surrounding objects and $\frac{1}{35}$ is created by the action of the agent, and when a body is cooled by the corresponding process, the whole heat abstracted from it, together with a quantity created by the agent, equal to about $\frac{1}{35}$ of this amount, is given out to the surrounding objects."

In editing his "Mathematical and Physical Papers," Lord Kelvin added the following interesting note under date of June 26, 1881: "The method of cooling air in unlimited quantities described in this article has been realised by Mr. Coleman, first, in refrigerators used for the distillation of paraffin, and, after that, in the Bell-Coleman refrigerator for carrying supplies of fresh meat from North America to Europe; in a great refrigerator recently sent out for the abattoir at Brisbane, Queensland, etc."

When Niagara is set to work for the benefit of North America through electric conductors, it will no doubt be largely employed for the warming of houses over a considerable part of Canada and the United States. But it is probable that it will also have applications, though less large, in other cold countries to multiply the heat of coal and other fuels, and to utilise wind and water powers (with the aid of accumulators) for warming houses.

The accomplishment of this form of heat control would enable us to construct uni-potential thermal systems, in which the high-potential factor would be secured directly by the heat of resistance and the low-potential factor by employing electricity as agent to operate by a motor a device like that outlined by Lord Kelvin. A system of this sort would appear to largely increase the central-station load-factor, and we would simultaneously introduce a large summer load by employing the same device, in reverse cycle, for cooling.

Of course many minor modifications of the two thermal systems outlined will suggest themselves. The gist of the whole matter is that for electric heating (or its synonym, central-station heating) to be economical a multi-potential thermal system must be operated, which is entirely feasible over moderate distances; or, assuming that electric central stations are to continue to run with the present deplorable fuel economy, the second or uni-potential system is the only feasible one, considering the whole subject in its broadest sense, and remembering that, while the device to accomplish the results sought is shown to be theoretically possible, it has not yet been entirely developed.

Where a complete thermal system is to be constructed, with coal or low-cost carbonaceous materials as fuel, the multi-potential combination is the direct way to secure high fuel economy and profit to the owner and user; and where only the mechanical equivalent of heat is available, as from motors, water powers, gas-engines, etc., we must interpolate a device for diffused heat control to heat buildings and water for use in same, in addition to the energy for high-temperature work, which we can profitably secure from direct heat of electrical resistance.

Results already accomplished in electric heating depend wholly upon the high-potential factors of the broad systems outlined. The time is not ripe for a comprehensive review of the collateral benefits derived from a highly localised form of heat energy, our concepts of the elasticity of which are only measurable by concepts of the rigidity of the ether. Instead of a concerted effort to create a field of use for the apparatus by constructing complete thermal systems, nearly all of the applications have been made as minor incidents in systems of electric lighting and power already established. This, of course, is logical pioneer work, but it fails to reach the vital elements necessary for full development.

The famous "Electrical-Heater Man" at the Franklin Institute in 1884 was the butt of the practical jokers among his co-exhibitors. The apparatus there shown was the first form of the electric car-heater with which to-day upwards of 5,000 cars are equipped. The status of the

Digitized by Google

electric car-heater is peculiar; it cannot be regarded as an economical device, but rather as a public requirement. An electric car is too small and crowded to admit of an economical and efficient isolated system of heating. Again, very little actual heat is required under average conditions, but rather a small amount of sensible warmth, uniformly distributed to each passenger on the basis of individual effectiveness. This can be met by an electrically-heated radiant at an energy consumption of less than 100 watts per square foot of surface, and in the common 20ft. car 20 square feet of radiating surface are sufficient for average conditions, and 35 square feet of radiating surface for extreme conditions.

Too little regard has been paid to the item of individual effectiveness in rendering cars comfortable. So much energy has been wastefully used in air-warming, even under average conditions, as to render the power consumption a most serious matter. The result is to give an unjust impression as to the cost of making cars habitable by electric heaters, and in the case of elevated roads using large cars in trains the item is a still more important one, as the energy for heating may equal or exceed that for propulsion. Again, in the case of elevated roads there seem no good reasons why the small rooms in the stations along the line should not be heated by the same agency as the cars, and in economical work of this magnitude we appear to be forced back to the uni-potential system using electricity as agent.

In small cars the heat of resistance is not excessively expensive. As in the case of the Vaudeville Theatre installation in London, there are peculiar local conditions which, as practice has proven, can be satisfactorily met with resistance heaters. But, while under ordinary circumstances we can heat bath and dressing rooms in residences by resistance heaters quite cheaply, considering intermittent use, we would not attempt to heat the whole house by the same means. If electric roads would locate their stations contiguous to business blocks and utilise their exhaust steam for heating purposes, there would be no difficulty in meeting the requirements of car and station heating on a large scale by resistance heaters. The *Railroad Gazette*, March 22, has given some interesting figures on the cost of heating cars by electricity, in which comparisons are made between heating large cars by electricity and by steam. As a general rule, the smaller the divisions of space and the more intermittent the use, the greater is the economy of electric heating, and we may include in this rule water heating as well as space heating.

Cooking by electricity is an important part of electric heating. In practice it means the accomplishment of high-temperature processes by resistance heaters, using other sources of heat energy for the hot-water supply and, preferably, water-boiling processes, as in vegetable cooking. One of the most complete analyses of this subject which has appeared was published in *Science* (September 15, 1893). The deduction is made that electricity at about 11 cents per horse-power hour is as economical as the common coal-range for cooking provided the electricity is used to heat an oven, the hot water being secured from outside sources. This appears to presuppose a radical change in cooking methods and apparatus, and, while this is undoubtedly proper in order to get best results, practice has seemed to require at the outset a more elastic system, in which the utensils conform to the generally accepted notions of what shapes and sizes should be.

To this end an experimental plant has been operated for 15 months in charge of a cook without special instructions as to the best method of operating the apparatus for economy, the desideratum being that good cooking shall be done and the utensil disconnected from the circuit when the cooking is completed. The equipment consisted of an oven, broiler, portable stoves, spider, plate-warmer, coffee-pot, and small tea-kettle. The result has shown that with apparatus conforming generally to the accepted notions of cooking utensils, the cost of electric cooking is practically equal to that of the gas and coal stove as generally run when electricity is supplied at four cents per horse-power hours. This does not show what can be accomplished under best control, but is a practical result in common usage.

The economy of electricity as a thermal agent in cooking is not doubtful, provided the uses to which the various forms of heat supply are put are proportioned in accordance with their heat equivalents, limiting electricity to high-temperature work. In combination with steam, both live and exhaust, there appears to be no reason why hotels and public institutions, operating their own plants so as to secure a multi-potential system, should not employ electricity in cooking very extensively, solely for the purpose of economy; for electricity in a well-designed isolated plant costs much less than four cents per horse-power hour, especially if we utilise the by-products of its generation in useful work, as would be the case in a complete thermal system. Ethical considerations in connection with electric cooking are of value after the economy and simplicity of the apparatus are established. Cleanliness, localisation of heat at predetermined temperatures, and coolness of the kitchen are important factors in connection with the servant problem. The use of electric cooking apparatus in cooking-schools is important, as constant temperatures are easily produced over extended periods.

In industrial work the applications of electric heating are rapidly multiplying. Nearly every manufactory of size has its own electric plant, and can secure electricity at low cost. In operating sad-irons and tailors' gooses, small glue-pots, soldering-irons, pitch-heaters, etc., sufficient compensating advantages are found to offset increased prime costs, in case they occur, and the outlook for extended applications in the industrial field is favourable. The ability to minutely sub-divide the heat energy, or, in other words, the elasticity of the system, makes it of special importance for use in manufacturing work.

It is impossible, within the prescribed limits of this article, to give more than a passing glance at the different factors in electric heating. We may perhaps best sum up the various sides of the problem as follows:

1. In constructing a thermal system we may employ electricity as the high-potential heat factor, by resistance heaters, or we may employ it as agent in operating motors to drive a suitable machine to secure diffused heat control.

2. In a multi-potential thermal system the useful heat available is pratically five parts low-potential heat and one part high-potential heat. In domestic life the ratio of heat required is found to be practically five parts diffused heat and one part high-temperature heat. Over limited distances we may therefore economically operate multi-potential thermal systems using electricity as the high-potential factor.

3. Electric heating is synonymous with central-station heating, presupposes the same generic elements, and requires for economy a complete thermal system, in which due regard is paid to proportioning the work done in accordance with the heat equivalents of the factors employed, all of which must be in such form as to constitute elements of a tele-thermal system.

4. Where the mechanical equivalent of heat only is available, as from motors, water powers, gas-engines, etc., we can economically employ electricity only for high-temperature work; for diffused heating on a large scale we must employ it as agent.

5. By constructing complete thermal systems, in which steam and electrical engineering are factors, the heat engineer can make electric heating a source of wealth to the owner of the system and a source of economy to the user of the heat energy, and therefore secure an advance on existing heating systems.

A Big Switchboard.—A big switchboard is about to be installed in the Government printing office, Washington, D.C. It will be made of Tennessee marble, set in an iron frame, will present a surface of nearly 1,700 square feet, and it will be fitted with special instruments, all the omnibus bar connections and clip-holders being of solid copper. Several tons of copper will be used in the connections. The switches will range in capacity from 800 to 1,000 amperes, and the board will be used for the distribution of current throughout the building for power purposes. Crocker-Wheeler electric motors will be laid down for the operation of all the printing presses and other machinery in the building. The Solar Electric Company, of New York, is supplying the switchboard.

MUNICIPAL ELECTRICITY.

This is the title of a paper read before the Municipal Engineers' meeting at Londonderry, but the paper might have better been given some other title. It is really of twofold character; in the first place pointing out that electrical engineers may very comfortably put aside much of the hair-splitting science of the electricians without detriment to the work undertaken, and, in the second place, the elementary knowledge that an engineer must know, is discussed. We had hoped upon first hearing the title of the paper to have had an exhaustive discussion from an official source of the reasons for and against municipal action in electric light matters. However, there are one or two points in this paper which may give rise to interesting discussion. The poor electrician is at first rather sat upon, but, like the astronomer, he has his uses, and it would be a sad day for electric progress if the pure electrician were to abate one jot of his energy. The astronomer provides the nautical almanack for the sailor, without which the latter would be unable to traverse the trackless ocean with the calm confidence he now does. The electrician, it is true, does not provide an almanack, nor does he usually move in advance so far as new departures are concerned, but he carefully analyses every new departure, points out the laws followed, indicates any variation from such laws, and generally puts weapons in the hands of the practical man which enables him to improve again and again the details of the new departure. The great difficulty is to decide upon the authority speaking. We cannot follow the *Pall Mall Gazette* in looking upon Herz as an authority, nor can we follow the *Scientific American* in its sweeping assertion that "No insulator of magnetism is known." We have long laboured under the impression that Lord Kelvin—then Sir W. Thomson—introduced iron-clad galvanometers for the purpose of insulating the needles from outside magnetism. We are sorry to learn that Faraday's, Webb's, and Thomson's experiments in this direction are erroneous. However, when we want to save a valuable watch from straying lines of force, we shall not hesitate to put it upon a bed of wool in an iron box and trust that it will in the end be found magnetically unharmed. However, the *Scientific American*, in its issue of August 10, gives us a good many more facts—query, fictions—of this nature.

Among electricians there are a good many debatable points, but upon many questions all are agreed. It is unfortunate that those who have not closely followed the various controversies cannot in general determine questions of agreement and non-agreement.

The most important question, however, for our readers, is in the suggested price per Board of Trade unit. The paragraph in question reads as follows:

"In the few remarks made by the writer in seconding a vote of thanks to the borough surveyor of Belfast, he suggested a threepenny rate per unit. Other people have come to this threepenny unit, and the writer is now inclined to halve it as a

Digitized by Google

reasonable rate in large towns. When electricity is to be had at three-halfpence a unit, a 16-c.p. lamp will keep lighting for thirteen hours for one penny."

In our opinion it is altogether bad to make statements of this kind. Ignorant people fasten on them, especially as the ordinary newspaper sub-editor revels in giving them a corner, and thus hundreds, if not thousands, are led to expect something altogether impossible in the majority of cases. We do not say that it is impossible here and there to produce electrical energy so that it may be sold at three-halfpence per unit, but we do say that in the majority of cases at the present time it cannot be done, and there is no likelihood of its being done during the lifetime of this generation. It is the average cost and the average selling price that should be the guide, rather than the lowest possible cost and the lowest selling price under the most favourable conditions that can be obtained. It is extremely annoying for a canvasser who calls upon the householder to ask him to introduce the electric light to be met with questions about the exceedingly high price at which the company or the municipality he is canvassing for charge for the energy supplied. The canvasser is met with the statement that such-and-such an authority says the price to large towns ought to be three-halfpence per unit, and here you are charging threepence, fourpence, fivepence, sixpence, or more per unit. These charges may be low when all the conditions are taken into account, but the householder is not the person to trouble himself about the existing conditions. He merely thinks he ought to get it at a certain price, and is annoyed to think that he cannot get it at that price, and refuses to patronise the new light. The majority of towns in the British Isles are compelled to fall back upon steam or gas engines as the motor for driving the dynamos. They have no water power available, hence the cost of generating a unit of electricity will probably be much larger under these conditions than for a town where water power is handy and otherwise running to waste. A careful examination of the cost of generation in the stations of the companies and the municipalities, will show that in very few instances is the actual cost of generation below the selling price which Mr. Perry suggests; but there are other expenses to be met besides the absolute cost of generation, and, roughly speaking, the selling price should never average less than double the cost of generation. We venture to direct attention to this statement at once, in the hope that a general refutation of its possibility will do something to ward off the harm that such a statement might lead to if left unnoticed. It will be recognised that the whole of this paper is, as we have previously said, more to give a general idea of the elementary knowledge required by municipal officers who have to report to their various authorities, rather than to exhaust any one particular point of the subject; and in this we think Mr. Perry is right—that most of his colleagues will be glad to have such a paper for consultation when examining this subject.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 177.)

INTERVIEW WITH MR. OSKAR VON MILLER.

Mr. Oskar von Miller, at one time manager of the German Edison Company and of the Berliner Elektricitätswerke, who, as is known, was commissioned to manage the technical part of the electrical exhibition at Frankfort-on-the-Maine in 1891, and there organised the famous transmission of energy experiments, has made use of the satisfactory results of these trials for the utilisation of the hydraulic powers of his native country, and the visit to one of these works—the Isarwerke—was one of the most interesting parts of the programme of the electrical congress. Owing to his various interests in different parts of Germany his time and person were much in demand, and I did not succeed in getting an opportunity for a quiet talk with him until the last day of the meeting. I was glad, after hearing his descriptions of the Isar works and other large engineering undertakings, to find that he had still a new subject ready for discussion with me. Having got Mr. von Miller away from his numerous friends, I said:

"What do you consider, Mr. Miller, the most striking recent advance in electrical undertakings in Germany?'

He replied: "One of the most important advances concerning the administration management of late years has been, in my opinion, the rapid increase of the use of electric light and power in small villages. I have designed several such plants for villages with 1,000 to 3,000 inhabitants which have been most successful."

"But," I asked, "how does the cost to the villagers compare with other illuminants at their disposal?"

"The rates I have recommended are such that the light is about as cheap as the petroleum lamp, owing. of course, to the high rate which is paid for petroleum at present in Germany. At a village I have in my mind, where the light has been started some three years, the charge is £1 per annum per 16-c.p. lamp simultaneously used, and as many lamps burn only by turns, 10s. to 12s. per lamp installed; for the latter the current can be used continuously day and night. As water power is used in the generation of the current, the cost of production is not in proportion to the actual number of units used by any lamp."

"About what size is the village you refer to, Mr. Miller?"

"The first small village, where an almost general use of electric light and transmission of force is made in a progressive manner, is Fürstenfeld-Bruck. It has a population of 3,000 inhabitants, and the total number of lamps fixed is now about 2,000. Besides the lighting, there is in the village a good demand for motors, of which there are some 18 with 36 h.p. at present at work. For these the charge is also fixed by the ratio output of the motor, and not by the energy consumed. The charge per horse-power and year in the different villages varies according to the cost of installation of the hydraulic power and the size of the motor; on an average the charge is £6 and £7. 10s. per horse-power per annum. These charges place power at the disposal of the various small users at prices which could not be attempted by other agencies?"

"How does the annual balance-sheet justify the installation in the case you refer to?"

"The annual cost of upkeep, including interest and amortisation of the capital, was about £1,000. The annual revenue would be at the preceding term about £1,400 for 2,000 lamps fixed, and about 36 h.p., the work being, however, carried out and managed by the community. No profit is calculated, and instead, the charges for light and power paid by the inhabitants are subject to discount."

"In the annual cost of the supply can you give me some idea of the principal items and their relative amounts?"

"In the annual cost of the supply the items of expense for paying interest and amortisation are about £600 for working expenses—that is to say, management, maintenance, etc., £400."

"What is the usual method of financing these village

Digitized by Google

installations in Germany, and to what extent are the local people interested in the success of the undertaking?"

"Usually, such small plants are erected and managed at the charge of the communities. There are, however, also several places—for instance, Schwandorf, Landsberg, and Tettnang—where private companies undertake the installation and administration of the work. The licenses they obtain run for a period of 30 years, with the obligation to supply the lighting of the streets at a specially cheap rate."

"What system of distribution do you usually adopt for village plants?"

"I have adopted, according to the quantity and distance of the power and the kind of consumption of current, the most different systems. At Cassel the system of alternating current and continuous current with accumulators is employed, there being a small distant power at disposal which must be accumulated to satisfy the consumption. In the Isar works I have employed three-phase alternating current, because there immense powers, requiring no accumulation, are chiefly supplied to factories, for which the three-phase alternating-current motor is of special advantage. For villages where use is made of a distant power for lighting and for small motors, I usually employ single-phase alternating current because of the simpler conductors."

"One more question I should like to ask you, Mr. Miller. What is your opinion as to the future influence of the Verband on the profession of electrical engineering?"

"The Verband will be able to produce very useful effects as representative of the general electrical interests as relates to the authorities. It will also obtain successes in technical views, if it occupies itself with common questions, and avoids as well as possible to interfere with individual interests of the members of the Verband. I set great value on the friendly, sociable relations of the electricians advanced by the annual meetings of the Verband."

THE ELECTRIC LIGHTING OF THE CITY OF LONDONDERRY.*

BY JOHN CHRISTIE, CITY ELECTRICAL ENGINEER.

The question of electricity supply, both for public and private lighting, is now becoming of so much importance to municipal engineers that when the author was asked to contribute something to this meeting of the association, he thought he could not do better than give you a brief description of our generating station, with details of the scheme as adopted here for the public lighting of this city. The idea of public lighting by electricity was first discussed by the Corporation so far back as March, 1888, but was allowed to drop. The matter was again brought up two years later, and it was then agreed to take out a provisional order under the Electric Lighting Act of 1882. In 1892 private companies made proposals to the Corporation, offering to lay down plant and run it under certain conditions. These proposals, however, the Corporation declined, and wisely determined to keep the monopoly of electrical supply under their own control. As the time wore on, and the Board of Trade required the Corporation to take some active steps in the matter if they wished to retain their powers, they, in September, 1892, called in Mr. H. W. Blake as consulting engineer to advise them on a scheme. The following year the Corporation finally decided to adopt a scheme for the public lighting of the city by means of arc lamps.

This scheme, prepared by Mr. Blake, was submitted to Dr. John Hopkinson, and on his approving of the specifications, tenders for the plant were invited by advertisement, accepted, and gone on with as soon as the permission had been granted by the Local Government Board to borrow the necessary estimated capital of £15,000. In the selection of a site for the station, the Corporation were particularly fortunate in obtaining on very favourable terms what had formerly been an old saw mill, situated in the Strand at a distance of some 700 yards from the centre of the city, having a frontage of 63ft. to that thoroughfare, and extending back 230ft. to the quay, and having an opening on to the river, thus affording every facility for storing our coal direct off the steamer, and also an ample supply of water for condensing purposes. On this site in the central portion there has been erected a substantial brick building, comprising engine-room and boiler-house, temporary gables being erected at each end, so that if any extensions are contemplated the buildings can be easily enlarged to accommodate the extra plant. The chimney stack, of handsome design, is octagonal in shape, 125ft. high and 5ft. in diameter, which is more than ample to suit any additional boilers that are ever likely to be required. At present there are only two boilers laid down. They were supplied by Penman, of Glasgow, and are of the Lancashire type, 26ft. long and 7ft. in diameter, constructed for a working pressure of 125lb. per square inch. They are well provided with all the usual mountings, mostly of Hopkinson's latest type. The feed-water arrangements comprise two duplex double direct acting pumps, each capable of supplying 900 gallons per hour against the maximum working pressure. The water is drawn from a storage-tank of some 20,000 gallons capacity, placed on the roof of the boiler-house, and supplied direct off the town mains. It can be delivered either direct or through the economiser, and all the steam and water pipes are in duplicate, in order to avoid as far as possible all risk of failure. The economiser is one of Messrs. Green's, and consists of 96 4in. tubes 9ft. long. It is placed on the main flue, being heated by the waste gases from the furnaces. Suitable by-pass flues and dampers are provided to regulate the temperature of the feed water or shut off the economiser altogether for cleaning or repairs.

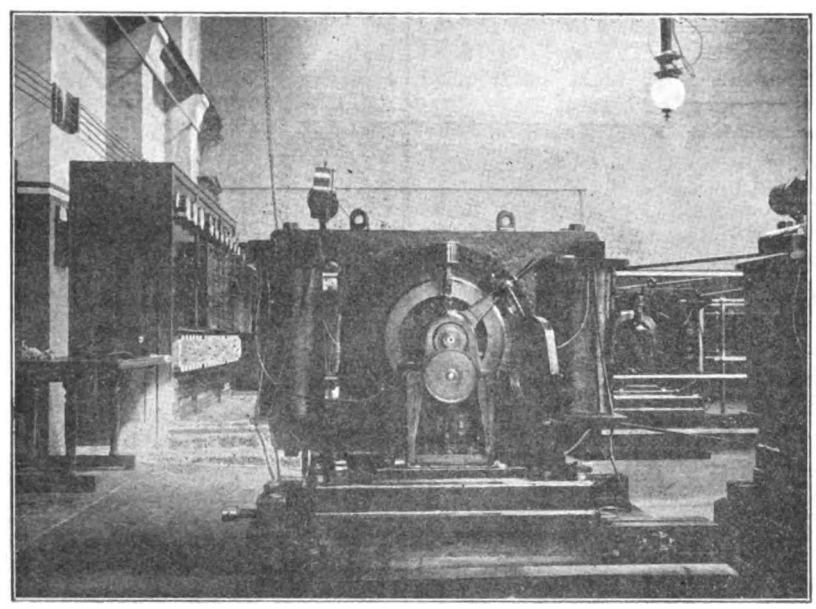
To prevent the tubes from becoming covered with soot and thus reducing the efficiency of the apparatus, a small horizontal engine is provided, which by means of suitable gearing actuates a set of scrapers, which slowly traverse up and down the tubes, keeping their surfaces clean and free from soot. As we use nothing but Welsh steam coal we have comparatively little soot, and the scraper engine, run for an hour or two at the beginning of each run, is sufficient to maintain the temperature of the feed water well up to 200deg. F. The steam is conveyed to the engine-room by two lines of 9in. wrought-iron pipe, having 6in. branch pipes to each boiler; both lines are common to each engine, and they are all thickly coated with a non-conducting composition to prevent loss from radiation. The pipes are provided with drain-pipes and steam-traps. In the engine-room are placed along one side three vertical compound condensing engines of 150 i.h.p., made by a local firm of engineers, Messrs. Brown and Sons. The diameters of the cylinders are, high-pressure 11in., low-pressure 22in., and the stroke 18in. The average speed at which they are run is 145 revolutions per minute. Each engine has a jet condenser of its own placed under the floor of the engine-room, the air-pump being operated off a crank disc on the end of the shaft. The condensing water is supplied to each engine by a separate 4in. cast-iron pipe laid direct to the river, each pipe being fitted with a clack valve, rose head, and mud-box. A 9in. cast-iron pipe serves as a common discharge to all the engines. An auxiliary injection pipe off the town mains is provided to each engine to assist at starting if the tide is very low or a suction pipe gets choked. The speed of the engines is controlled by Hartnell's patent automatic expansion governor fitted on the crankshaft, which, by shifting the angle of advance of the high-pressure eccentric, varies the cut-off of the valve to suit the load. The distribution of steam is effected in the high-pressure cylinder by a piston valve, admitting the steam in the middle and exhausting at the outer edges, and in the low-pressure cylinder by an ordinary trick slide valve; by this arrangement the high-pressure piston gland is the only one which is subjected to the full working pressure. All the bearings are of ample size, and are provided with a suitable means to take up the wear. The flywheels are 8ft. in diameter and 24in. broad, and each weighs about three tons. By means of two 10in. leather belts, each engine drives two dynamos, placed on sliding rails one behind the other.

The dynamos are of the constant-current series type, made by Messrs. Siemens Bros. and Co., Limited, London. They are designed for an output of 10 amperes at 3,000 volts at 750 revolutions per minute. The machines have ring

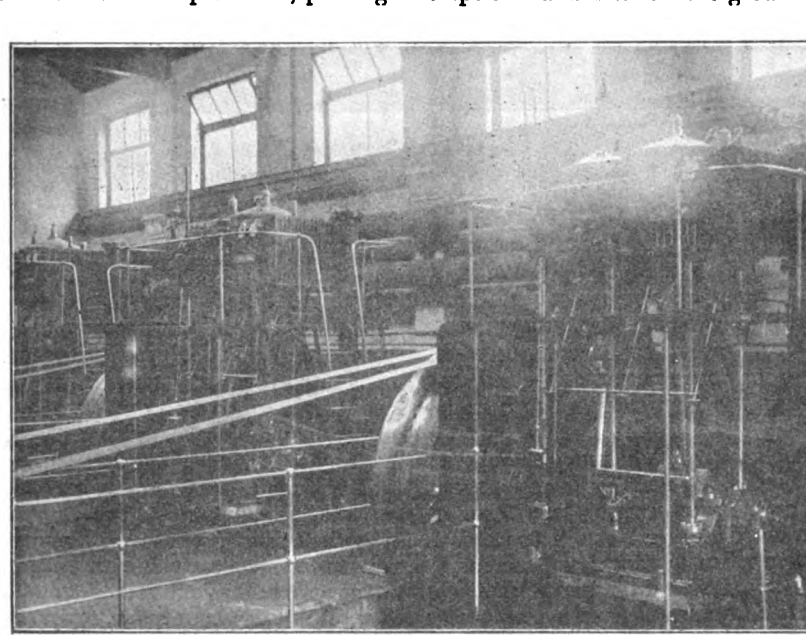
* A paper read before the Incorporated Association of Municipal and County Engineers at Londonderry.

Digitized by Google

armatures rotating in a double magnetic field, and are fitted with copper commutators 18in. diameter, divided into segments, and insulated with mica. We have had them running constantly for nearly 18 months at 2,500 volts, and often having them subjected to the most severe strains possible—they have given no trouble whatever, the sparking is not excessive, and the wear on the commutators very small. To keep the current constant, a very ingenious regulator is provided, which automatically varies the voltage to suit the number of lamps on circuit by rocking the brushes back or forward; with these regulators in gear it is almost impossible to get more than 10 amperes for any time, and they give the current just as well on short-circuit as when the whole resistance of the circuit is on. Last winter we had ample opportunity of testing them through the high winds which were so prevalent, putting lamps to work temporarily, and also when two faults would sometimes come on the cables at one time, cutting out 10 or 20 lamps. From the dynamos the current is led to the switchboard by means of insulated cables laid in trenches under the engine-room floor. The switchboard, also made by Messrs. Siemens and Co., is composed of slate panels, in polished wood frames. It is arranged for six dynamos and four circuits, and is provided with short-circuit field switches, double-pole fuses, and a Swinburne electrostatic voltmeter to each dynamo; each circuit having a Siemens ammeter, double-pole fuses, and a Thomson-Houston lightning arrester on each end. By means of a plugboard any circuit can be run off any dynamo. The lighting of the city is divided into two sections, each section having two circuits with lamps arranged alternately on different circuits. At present we have the lamps arranged on the four circuits as follows: 40, 43, 41, and 48, or 172 in all; but extra lamps will most probably soon be looped in to bring the numbers on each circuit up to over 50, and do away with some more of the gas lamps which still exist in some of the smaller streets. The cables consist of $^{7}/_{16}$ copper strand heavily insulated with vulcanised indiarubber, served with a covering of bitumenised jute, armoured with galvanised steel wires, the whole being covered with jute steeped in a preservative compound and laid in the ground direct. The armouring is earthed at every lamp, and also at the station ends. There are some 34 miles of this cable laid, the longest circuit being about nine miles, and the area lighted is, I think, one of the largest in the country. During the first six months after the plant was taken over by the Corporation we had a most unfortunate time of it through failures of the lamp cut-outs, cables, and other causes incidental to the start of such a large scheme. For a long time this made the electric light most unpopular with many, but Messrs. Siemens successfully surmounted all the



View of Dynamos.



View of Dynamos, showing Automatic Constant-Current Regulator

Digitized by Google

many difficulties as they cropped up, and in the very depth of winter entirely relaid the whole of the cables without interrupting the lighting of the city. All these failures are happily a thing of the past, and now we rarely have even a single lamp failure reported. All the lamps are of the well-known Brockie-Pell double-carbon 32-hour type, so that in winter they only require trimming every second day, whilst in summer once a week suffices. Each lamp has fitted within itself a cut-out, which, should the carbons burn out or the rods hang up from any cause, automatically cuts out the lamp from the circuit and forms a by-pass for the current to go on to the next lamp. The lamps are fixed on ornamental cast-iron pillars 25ft. high, and pitched from 75 to 250 yards apart. In the base of each pillar, inside a locked door, an isolating switch is provided, by means of which any separate lamp may be extinguished, quite independently of any of the others on the same circuit.

A brief description of our method of detecting faults on the circuits may be of interest to some of you. Daily insulation-resistance tests of all the circuits are taken, and if any one shows below the normal it is carefully watched; should it become dangerously low, the position of the fault is first roughly located by means of a Kelvin electrostatic voltmeter of the ordinary type reading up to 6,000 volts; the weights on the vane are adjusted so that the scale reads 50 volts per division. One terminal of the instrument is then earthed, and the other terminal connected to the positive and negative ends of the faulty circuit, and two readings obtained, which, assuming the voltage per lamp at 50, reads directly the number of lamps from either end, about which the fault exists. By referring to the map we can at once go to almost the exact lamp, and by freeing the ends at the switch tell by means of a detector whether the fault lies in a lamp or a section of the cable between two lamps. This method I find saves an immense deal of trouble, rendering it unnecessary to split up a long circuit into several parts until the faulty one is found; and if the readings are carefully taken we can always spot the section within two lamps either way. If the fault proves to be in a lamp it is immediately remedied by replacing it with a spare one, and if in the cable and of low enough resistance it is at the earliest opportunity burned out dead to earth by temporarily earthing one end of the line at the station, when by means of the loop test taken on the section with a portable testing set, the exact position of the fault is located and cut out. I am glad to say, however, that such faults never occur in the cable we now have through any inherent weakness of the insulation, but have always been clearly traceable to pick marks caused by some careless workman, when opening the streets, accidentally striking the cable and neglecting to report it.

The cost of the whole scheme up to the present amounts to between £18,000 or £19,000. The difference between this amount and what was first estimated is chiefly due to extensions of the scheme entered into after the contracts were settled. The end of our financial year is not up till November, and the author regrets that he cannot give you the exact cost of the public lighting. In winter during the long nights the works cost per lamp hour were as low as ·65d., and in summer, when the runs were shortest, they reached as high as 1·70d. per lamp hour. So far as can be judged, the total costs, including everything, should not much exceed £19 per lamp per annum, which, considering the number of hours we run (over 3,000), is by no means excessive. No attempt has yet been made by the Corporation to introduce private lighting, except in the Guildhall and clock, which are both lighted by lamps looped off the street mains, but as they have every facility on the site of the present station for the accommodation and working of all the necessary plant for private lighting, and as the town is particularly well situated for the working up of a most lucrative electricity supply business, the author has no doubt that before long they will be following the example set them by nearly all other leading municipalities, and wisely keep the valuable monopoly of supplying electricity to the citizens in their own hands by extending their present station and laying down suitable machinery.

UNIPOLAR INDUCTION.*

BY REGIERUNGSRATH DR. C. L. WEBER.

An article by Prof. C. Arnold on alternating-current machines with stationary winding† is prefaced by some remarks on unipolar induction. The latter subject has also recently been elaborately treated by Prof. Lecher, of Innsbrück.‡

While Lecher, on the basis of experiments extending over many years, claims to have come to a definite conclusion as to the explanation of the phenomenon in question, Arnold admits that the majority of the appearances can be explained by the specific reciprocal results, but finally declares for those which Lecher does not deem to be trustworthy. For this reason a short consideration of the subject may be justifiable, for it must be puzzling to anyone who is not perfectly acquainted with the details of the question when, regarding a matter which crops up daily in practical work, two views of so fundamentally opposite a character are maintained.

The question is as follows: A cylindrical magnet revolves

* *Elektrotechnische Zeitschrift*, August 15, 1895.

on its geometrically coincident magnetic axis. Will the lines of force of the magnet rotate with it, or does the magnetic field stand still? The above-mentioned article by Lecher is without doubt the most careful and most elaborate investigation of the subject of unipolar induction which has been published in the last 10 years. As they cannot again be recorded here, it may be mentioned that Lecher repeated nearly all the experiments hitherto made bearing upon the question and critically examined them, finding thereby that in the case of all previous investigations the observations could be explained by both the one and the other theory.

Finally, the following experiments, which are to be considered as conclusive, were devised and carried out by him. A magnet excited by a fixed coil is divided into two parts, I. and II. (Fig. 1), which can individually be rotated on the axes, S N, S^1 N^1. Corresponding axle shafts are arranged at N S, N^1 S^1. At the same points, and also at *b* and *d*, are the sliding contacts, *a*, *b*, *c*, *d*, *e*, which can be connected with a galvanometer, G. The direction of the lines of force has to be conceived in the manner indicated. As is known, there flows, if both parts rotate together along a path, *a* G *b* or *a* G *c*, a current which, in the acceptation of a revolving field, can be imagined as having originated in the fixed galvanometer leads; in the supposition of a fixed field, in the rotating mantle surfaces and in the radial parts of the iron core. The following outcome of an experiment can also possibly be explained by both views. Only magnet II. revolves, the galvanometer being first at *c d*, next at *d e*. The issue in both cases is the same. It can here be taken with Faraday that in both instances the same amount of induction takes place in the actuated con-

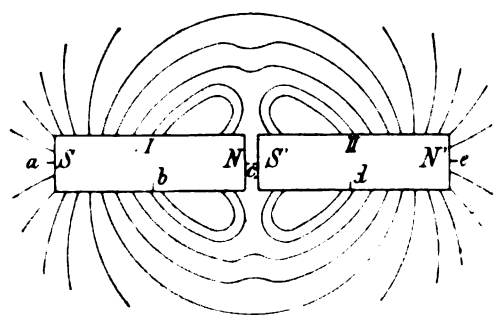

Fig. 1.

ducting parts of the magnet on the fixed field being cut, as, according to the other view, that the total of the E.M.F. induced in the two fixed circuits in both cases is the same. The course of the lines of force certainly causes the latter explanation to be considered with doubt, but the determination of this course is generally of an uncertain nature.

On the other hand, the observations about to be described cannot be brought into consonance with the theory of rotating lines of force. If Lecher altered the last mentioned experiment, so that not only magnet II., but also magnet I. revolved, either in the same direction as, or in the reverse direction to, II., the galvanometric results were the same as if I. were stationary. According to Faraday, this is immediately clear, since the magnetic field remains continually at rest and the actuated conductors connected with the galvanometer only belong to magnet II. The contrary happens if the lines of force revolve with the magnet; for then, if I. be set in motion, an influence of the galvanometer circuit, *c* G *d*, is perceptible, as the lines of force emanating from and actuated with I. reach into the circuit *c* G *d*.

Clearer is the following experiment: If *b c* is at the galvanometer and I. rotates while II. is stationary, exactly the same current is obtained if *b d* is at the galvanometer and I. again rotates, II. being stationary. If, however, both magnets are revolved in opposite directions, double the amount of current is the result.

Finally, Lecher connected the sliding contacts *a* and *e* with the galvanometer, so that the wires formed the extension of the magnetic axis. If, now, I. rotates alone, a current of 33 is obtained; if II. rotates alone, and in the contrary direction, the same result is attained; if both magnets are simultaneously revolved in the opposite direction the total of the two previous currents is the result.

Arnold has a new, but impossible, theory. He says: "It must be considered, if only the one magnet revolves, that then its lines of force rotate at only half-speed, and that generally the speed of the angle of the magnetic field does not correspond with that of the revolving iron mass, but that the rate of both is dependent upon the ratio of the actuated to the total iron mass."

If it be sought to follow this idea it will be necessary, in the first place, to at least look upon the lines of force flowing within the iron as bound to the iron and revolving at the same speed. Then, however, a variation of speed must occur at the point of exit, and therefore a tearing-off of each line of force and a sliding away of its termination at the magnet surface. Likewise must then at the place of

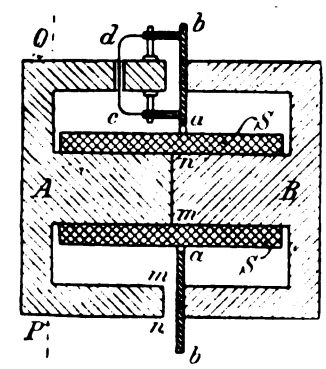

Fig. 2.

entry in the stationary or opposite rotating part of the magnet a similar inconstant point in the lines of force with the half angle speed glide over the surface of the iron. The lines of force in the various parts of the course must exhibit a triple phase: (1) within the iron they have the same speed as this; (2) outside of it they show the half, or generally another speed; (3) at the points of transition a sudden change in the speed occurs.

The idea of a stationary field with rotating iron core has nothing overstrained in it. The lines of force are comparable to a condition of the ether, which is influenced by the properties of the surrounding matter. If, however, neither the magnetic excitation nor the exciting capacity of the material alters in a given direction from point to

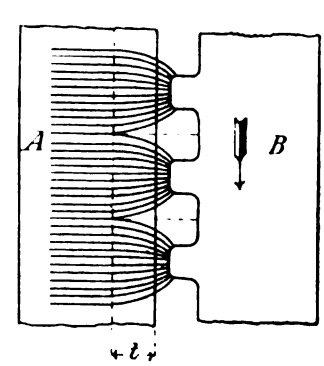

Fig. 3.

point, so will also the condition of the ether remain unchanged. A ground for a rotation of the field of force does not therefore exist with the rotation of a magnetic body, whose geometric, magnetic, and rotation axes coincide.

If we take two bell-shaped iron cores which are excited by a common coil and can rotate independently of each other, something, as in alternating-current machines, we find that between the two outer mantle surfaces gaps remain which can take up induced coils (Fig. 2). So long as the dividing surfaces run continuously throughout, the above considerations find application without further difficulty, and lead to the representation of a fixed magnetic field, by which, in simultaneously rotating parts of conductors (as, for example, in the disc *a b*), radial currents are induced; but if the dividing surfaces—in

Digitized by Google

the first place on one side only—are not continuous (Fig. 3), the idea of the simultaneously rotating lines of force, shown as incorrect, again obtrudes itself. A little consideration, however, manifests that this theory is here quite unnecessary and liable to lead to error. This is best recognised by passing over to the next drawing, Fig. 4, where both surfaces are furnished with teeth. A is rotating and B is stationary; you fix an individual tooth in your eye and conceive that it on the rotation of position 1 pushes forward into position 2.

If here the lines of force rotate with the iron mass, equally as many lines of force should pass through this one tooth in position 1 as if it after a short time had reached 2. This will in reality in nowise be the case; we are rather shown that the tooth in question in position 2 on account of the large air-gap carries considerably fewer lines of force. The induction consequently which a coil placed on the tooth experiences proceeds here not from a rotation of the lines

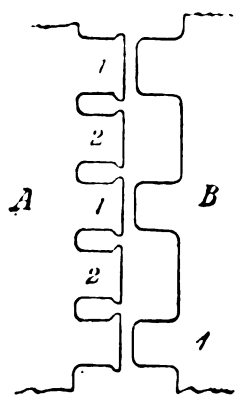

FIG. 4.

of force in the direction of the field, but from a fluctuation of the flow of force parallel to the rotating axis. The majority of the lines of force produced will now take their way through the one tooth, now through the other, accordingly as the one or the other path offers at the moment the least amount of resistance. The theory that here the lines of force should rotate at half-speed is obviously upon this hypothesis not feasible.

For the estimation of the eddy currents set up, and of the magnetisation energy, and for the selection and arrangement of the means to be used for the avoidance of these losses, it is a point of great importance whether in machines of the last-named form a side by-pass of the lines of force or a deviation in the direction of the rotating axis is presupposed. If you, in the last-mentioned case, look upon the actuated part somewhat as the field magnet of an alternating-current machine, the fluctuations mentioned will pass for armature reaction.

ELECTRICAL MACHINERY FOR MINES.

A meeting of the Midland Institute of Mechanical Engineers has been held at Barnsley, at which Mr. Rankin Kennedy read a paper on "Electrical Machinery for Mines," in the course of which he discussed the relative merits of continuous and alternating current motors. Owing to the liability to sparking, it was necessary to have continuous-current plants in workings boxed in airtight cases to prevent gas being ignited by the sparks at the brushes. The alternating-current system, if ever used, would undoubtedly be a polyphase system, in which polyphase alternators, with continuous-current exciters, would be used for generating the currents in two or three phases. The motors would be without commutators or brushes, and, being sparkless, would not require to be enclosed. In this system the pressures were not fixed, and any pressure desired, high or low, could be obtained with certainty and efficiency by a transformer. These statements sounded as if an ideal system had been reached, and theoretically it was all right, but in practice it had not reached the theoretical limits, as the generators were more costly than continuous-current generators. The necessity for separate continuous current exciters was a serious drawback, and the motors at present available were more costly than enclosed continuous-current motors. Polyphase motors required sliding contacts and brushes to be inserted as resistances when starting. So long as a sliding contact remained the motor was no better than a continuous-current motor. It was possible to make the system a success, both electrically and commercially, and in time, no doubt, the various drawbacks would be overcome. Considering polyphase motors fuse in mines where gas accumulates, he said that where motors of less than 15 h.p. were required the Kennedy polyphase motor could be used successfully without sliding contacts, and could be applied to the working of pumps and coal-cutting and haulage machinery underground with perfect safety, and for larger powers the same motor might still be used without sliding contacts if allowed to start under a small load by using a friction clutch or fast-and-loose pulley. The chief difference between this and other polyphase motors was that the two currents were quite separate on the motor, and mutually protected each other. In the combined system the author proposed to use a modified continuous-current generator, capable of supplying continuous current and polyphase currents simultaneously, it being possible to make a generator capable of supplying continuous, alternating, and polyphase currents as simple, cheap, efficient, and reliable as the continuous-current dynamo, being, in fact, the same machine with a few simple modifications. These would give 90 per cent. of efficiency, and would be a great advantage in the use of electric light or power in connection with collieries.

THE FIRST BRITISH ELECTRIC MOUNTAIN RAILWAY.

A Douglas correspondent, writing on Wednesday, says that on that day, in the opening of the Snaefell Mountain Railway in the Isle of Man, there was completed an engineering work of considerable magnitude and importance. The railway commences at the village of Laxey, seven miles from Douglas, and terminates on the summit of Snaefell, at a height of 2,000ft. above sea level. The total length of the line is 4¾ miles. The actual height ascended is 1,820ft., making the ruling gradient 1 in 12. The gauge is 3ft. 6in., and the line is double throughout the entire length. The carrying rails are of steel, and weigh 50lb. to the yard. A centre rail, known as the "Fell System," has been adopted to ensure absolute safety to the descending trains. It is a double-headed rail, weighing 65lb. to the yard. The rail is carried on wrought-steel chairs, to which it is bolted. The chairs are fastened to the cross sleepers by four fang bolts, a chair being placed on every sleeper. The Fell system is also utilised for tractive purposes as well as for brake power. Horizontal wheels are driven by a separate motor, enabling heavier loads to be carried at a greater speed on steep inclines. This system was applied to the crossing of the Mont Cenis Pass of the Alps before the great tunnel was completed, and it has been successfully working in South America, and has also been adopted by the New Zealand Government for crossing mountain ranges. On leaving Laxey the line commences immediately to make the ascent, skirting the steep slopes of Laxey Glen. The picturesque little village of Laxey and the great wheel are seen from innumerable points of view, and they are not lost to sight until the train attains a height of more than 600ft. above the sea. At this point, on looking back through the Granane cutting, a lovely peep is obtained of the open sea, which is not again in view until it is seen on the opposite coast of the island. Now the heaviest and most costly portion of the work is reached, the line passing through a succession of cuttings through the rock and over high banks, supported by massive retaining walls. The ground is rocky and precipitous, and the Laxey river, which runs almost within a stone's throw, is several hundred feet below the line. At a distance of 2½ miles from Laxey the Snaefell mines are seen, directly on the opposite side of the valley, lying some 300ft. down in the hollow; and half a mile further the Snaefell Hut is reached, which has for some years served as a wayside hotel for travellers. Now we are on the mountain, and the line winds—always climbing—first round to the west side, whence Sulby Glen can be seen, then to the north, bringing Ramsey and the Point of Ayre into sight, then to the east, showing you Laxey again, and lastly to the south, where it terminates, having in a distance of 1¾ mile from the Hut made a complete circuit of the mountain. The line will be worked entirely with electricity as the motive power. The whole of the plant has been designed and constructed by Messrs. Mather and Platt, Limited, of Manchester. There are four Lancashire boilers, each 26ft. long and 6ft. 6in. in diameter, working at 120lb. pressure per square inch, and

Digitized by Google

capable of giving steam sufficient for 700 h.p. There are five compound horizontal engines, and each independently drives a Mather and Platt dynamo. The dynamos supply the current at 500 volts pressure. The generating plant is erected in a station close to the line, about 2¾ miles from the Laxey terminus. At the latter place there is also a large accumulator station containing 246 cells of the patent chloride protected type. The accumulators absorb the spare current generated by the dynamos and distribute it to the line as the load requires. Messrs. Mather and Platt first introduced this system on the Douglas and Laxey Electric Tramway, where it has proved a great success, contributing largely to the economical and regular working of the line. It has also been adopted by them on the Stockholm and Djarsholm Electric Railway. The passenger cars are 35ft. in length, and will seat 48 passengers. The seats, which have movable backs, are placed transversely, so that the passengers may face the direction in which they are travelling. Each car is carried on two four-wheeled bogies. Each axle is driven by a Mather and Platt motor, capable of driving the car at a speed of eight or nine miles an hour on the ascending grade. Absolute safety is obtained against the cars leaving the rails. It would be an impossibility for the flanges of the carrying wheels to mount the bearing rail whilst the guide wheels are in play. A powerful centre-rail brake is fitted to each car, the action of which is to grip the centre rail itself. Whatever speed may be obtained in descending, no danger can possibly arise, as the car can be stopped within a few seconds from the brake being applied. The works were commenced in January last, and, considering the severity of the weather during the first three months of the year, and the amount of heavy rock-cutting that has had to be executed, they must have been pushed forward with the most resolute energy. The engineers to the undertaking are Mr. Alexander M'Kerrow and Mr. G. Noble Fell, of London, who have had much experience in the construction of mountain railways. Mr. Fell himself laid out the line, and has personally superintended the construction of the works; and Mr. R. N. Willis (for Messrs. Mather and Platt, Manchester) has had charge of the electrical department. During the opening day, though the weather was unfavourable and a thick mist prevailed, many tourists ascended the mountain by the railway. The cars ran with remarkable smoothness, and gave perfect satisfaction.

COMPANIES' MEETINGS AND REPORTS.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

An extraordinary meeting of this Company was held on Friday last, Mr. J. S. Forbes presiding.

The **Chairman** moved the confirmation of resolutions passed at an ordinary meeting held on July 29, to the effect that the articles of association be altered so that the amount from time to time declared by the Board as available for dividend be applied in such a way that there should be first set aside a sum equal to a preferential cumulative dividend of 7 per cent. per annum on the aggregate amount for the time being paid or credited on the "A" shares, and that out of the sum so set aside there should be paid a preferential cumulative dividend at the rate of 5 per cent. per annum paid on the amounts paid or credited as paid on the "A" shares without distinction.

The motion was unanimously adopted.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY.

The fou·teenth general meeting of shareholders in this Company was held on Wednesday, Mr. W. Neale, the new chairman of the Company in succession to Mr. Ebbsmith, presiding.

The balance sheet showed a working profit of £55,924, or £3,120 more than in the preceding year, and the **Chairman**, in moving the adoption of the report and the directors' recommendation for the payment of a dividend of 3 per cent. on the written-down capital of the Company—equal to 1½ per cent. on the subscribed capital—drew a distinction between the steam and cable sections as the profit-earning and the electric and horse sections as the unprofitable section of the Company's undertaking. The steam cars had run, he said, 50,544 miles more, and carried 610,508 more passengers, and earned £2,469 more than in 1893·4, whereas in almost every item of expenditure economies had been effected. Seven hundred and five pounds had been saved in fuel alone, mainly by the substitution of 12 new Kitson engines for old Beyer-Peacock engines, and the average consequent saving had been ¾d. per mile. The gross earnings of the steam department were £82,749 and the working expenses £48,348, leaving a profit of £35,351. The cable section showed still better results. The mileage was 743,805 miles, an increase on the year of 44 955 miles; the passengers carried, 6,842 538, an increase of 143,062; the earnings £36,744, an increase of £670; and the expenses £16,830, leaving the profit on the section £19,914. The electric department had run 138,925 miles, a decrease of 198 miles; carried 1,154,345 passengers, or 149,488 less than in the preceding year; the earnings were £9 093, a decrease of £641; and the expenditure was £10,828, involving a loss on the year's working of £1,735. The horse department had run 152,895 miles with tramcars and 552,164 with omnibuses, and carried respectively 1,320,344 and 2,973,983 passengers—in the former case a slight increase and in the latter a decrease. The omnibuses showed a decrease in receipts of £1,677, and the tramcars an increase of £313. The earnings of the two services amounted to £27,888, and the expenses to £25,494, leaving the profit only £2,394 The cost per working mile was—for steam 9 11d., horse traction 8 67d., cable 5 43d., and electricity 18·43d. The Chairman pointed out, with regard to the electric service, that it had been greatly disturbed by the severe weather of the last winter, and also by the disastrous fire which occurred during the year, and the directors hoped, by being able to purchase their batteries at a less cost and by other economies, to bring the section to a paying condition in a short time.

Mr. Ebbsmith added that it would not be a bad speculation for an electric tramway expert to relieve the Company of the section and guarantee them against any loss on it.

The **Chairman** pointed out that the cost of maintenance and renewal of way had been an unusually heavy charge during the year, especially on the steam routes, and as it had all been charged to revenue the divisible profit was made very small. A dividend of 3 per cent. would absorb £5,820, the dividend on 5 per cent. guaranteed stock £5 000, £10,000 was invested outside the Company on reserve fund, and £671 was left to be carried forward.

The report was adopted and the dividends recommended declared, and subsequently there was a long and somewhat acrimonious discussion on matters of policy between members of the "old Board" and the two new directors who joined it a year ago as the representatives of the Shareholders' Association.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

The following is the report of the directors to be submitted to the shareholders at the fifth ordinary general annual meeting, to be held at the Cannon street Hotel, on Monday, the 26th inst., at 12 30 p.m.: The directors beg leave to submit herewith the accounts and balance-sheet for the years 1893 and 1894, but at the same time desire to point out that they are only responsible therefor as from November 21, 1894 (the date when the management of the Company's affairs was placed in their hands by the Court) to December 31 of the same year, or less than six weeks out of the two years. The receipts of the 12 months ended December 31, 1894 exceeded those of the previous year by £527. 17s. 1d. The receipts of the 12 months ended December 31, 1893, exceeded those of 1892 by £2,509 19s. 1d. The receipts per car mile for the year 1894 were 11·61d., against 11 90d. for 1893, and 13·47d. for 1892. The decrease is the result of the increased car mileage run on the electric sections. The average fare per passenger carried in the year 1894 was 1·43d., and in the year 1893 1·45d., as against 1·48d. in 1892. The total expenditure in the year shows an increase of £1,653. 5s. 2d. as compared with the year 1893, and the total expenditure for 1893 shows an increase of £2,294. 4s. 2d. as compared with 1892. These large additions to the expenditure have been largely caused by the policy of the late Board in consenting to the appointment of receivers and managers in May, 1893, one of whom was the chairman of the Company; £1,455. 3s 1d. has been received by these gentlemen for remuneration. No interest was in arrear at the time of the appointment, nor was there any real necessity for such proceedings, which it is believed were instigated for the express purpose of preventing the control of the Company's affairs passing into the hands of shareholders hostile to the previous administration The directors do not propose in this report to deal with the difficulties placed in the way of the Shareholders' Protection Committee before the retirement of the former Board could be brought about in June of last year, when on taking office the directors found themselves face to face with an application to break up and sell the undertaking, which meant wiping out the shareholders, both preference and ordinary alike. At this crisis, and believing as they did that the proceedings against the Company were not in the interest of the main body of the debenture-holders, but were likely to lead to results disastrous to both debenture-holders and shareholders, the directors determined, even at their own expense, to use every endeavour to preserve the undertaking, and after an important litigation succeeded in obtaining the judgment of Mr. Justice Kekewich, affirmed by the Court of Appeal in favour of the Company, and the discharge of the receivers and managers, and a declaration from the Court that the tramway was a public undertaking, and could not be broken up or sold in the same manner as an ordinary commercial concern, and that a receiver of the net earnings only could be appointed. As this decision affects tramways throughout the kingdom, its importance cannot be overestimated. In consequence of this reverse in the Chancery Division, the plaintiff in these proceedings commenced a further attack upon the Company in the Queen's Bench, but met with no better success, his action being stayed with costs by the Court of Appeal. Immediately on taking office, the directors resolved to commence an action for damages at the instance of the Company against Mr. Joseph Ebbsmith and Mr. Wain, the late chairman of the Company, in which £15,000 damages and other relief is claimed, and this action is being pressed to trial as rapidly as its important character will allow. Other proceedings have also been taken with a view to the recovery of money which the directors contend should never have been paid. In furtherance of the policy upon which they were elected, the directors repudiated on behalf of the Company the contract of February 26, 1892, and litigation with the Electric Construction Company, Limited, is now pending with reference thereto. This contract meant absolute ruin to the Company, and the directors are advised that it will not

Digitized by Google

be enforced against the Company. The directors have had the reorganisation of the Company under their constant and careful consideration. They were of opinion that the traffic superintendent and the draughtsmen were both unnecessary, and their services were accordingly dispensed with. Mr. Alfred Dickinson has resigned his position, and Mr. J. J. Robins, who has had considerable experience both in tramway and electrical work, has been appointed in his place, and, apart from other considerations, these alterations will result in a substantial annual saving to the Company. The directors ever since their appointment have had great and arduous difficulties to cope with, but they are gradually being surmounted. Winding-up proceedings have been attempted and various efforts made to break up the Company, but the directors have up to the present successfully met and defeated all such endeavours. The directors also find that there is a great and pressing necessity to provide some new method of traction for those sections of the line which are now worked by steam engines, the license to use which expired during the *régime* of the former Board, but which has been renewed by the Board of Trade from time to time. The litigation with the Electric Construction Company, Limited, above referred to, has hitherto presented an insuperable difficulty in formulating any satisfactory scheme for improved traction, but so soon as that difficulty is disposed of the directors propose to formulate a scheme which they trust will meet the views of the Board of Trade and the local authorities, and which will, while assuring a return of the further capital invested, offer a reasonable prospect of a dividend to the present shareholders. The directors have decided to discontinue the goods traffic, which has always been a source of loss to the Company. The directors regret that, owing to the circumstances above indicated, they were unable to hold this year's annual meeting in March. It is therefore necessary for the shareholders to sanction the meeting being held this month, and for that purpose an extraordinary general meeting of the shareholders will be held at the same place ten minutes before the time appointed for the annual meeting. Those shareholders who are unable to attend these meetings, but desire to support the Board, will please sign and return both the enclosed proxy forms. Under the provisions of the Company's Act one of the directors, Mr. W. Somers L. Schuster, retires by rotation, and being eligible, offers himself for re-election. The auditors, Mr. Henry Spain and Mr. B. W. Hardcastle, retire, and offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Thorne (Yorks.).—The Thorne Parish Council invite tenders for the lighting such part of the town of Thorne as is comprised in the lighting area from September 1, 1895, to April 30, 1896. Tenders to be sent in by 27th inst. to Mr. C. Waller, clerk.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895, for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Bedford.—The Urban Sanitary Authority invite tenders for the supply of vulcanised rubber cables, in accordance with the specification which can be obtained from Mr. T. S. Porter, clerk to the Authority, on payment of a fee of 5s. for each copy. Sealed tenders, endorsed "Electricity," to be delivered at his office not later than September 4.

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f. This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas. Provisional security 10,000f.

Cowes.—Tenders are invited by the Urban District Council for laying down an electrical plant of sufficient capacity to keep burning at the same time 2,200 8-c.p. lamps, and also for public lighting and the laying of mains to accommodate 3,000 lights at the same time. The length of the road to be lighted is about a mile. Particulars can be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., engineer to the Council, Cowes. Tenders are to be delivered by August 27.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Killarney.—The Commissioners for the Control of Lunatic Asylums, Custom House, Dublin, invite tenders for the electric wiring of the Killarney District Lunatic Asylum, the same to be connected to the supply mains (high tension) of the Killarney Electric Lighting Company. Forms of tender will be issued on application to the above Commissioners on deposit of £1, which will be returned to all persons who have sent in *bonâ fide* tenders on return of specification. The plans and specification can be seen at the asylum or at the office of the engineer, W. Leake, Esq., 30, Victoria-buildings, Manchester. Tenders are to be sent in by 30th inst.

Sunderland.—The Corporation invite tenders for (*a*) high-tension and low-tension concentric cables; (*b*) cast-iron pipes and box frames and covers; (*c*) stoneware casing, boxes, and bell-mouth protectors; (*d*) high-tension transformers for alternating current; (*e*) meters for alternating current. Specification, etc., can be obtained on payment of one guinea at the office of the borough electrical engineer, Electric Supply Station, Sunderland. The deposit will be refunded on receipt of the specification and conditions of contract with a *bonâ fide* tender. Tenders should be delivered at the town clerk's office by Monday, 26th inst.

Portsmouth.—Tenders are invited for wiring and lighting by electricity the police stations at Buckland, Southsea, Portsmouth, and Portsea. Full particulars can be obtained, and specifications can be seen, at the Town Hall, where a form of tender can also be obtained. Form of tender supplied to be completely filled in and sent under cover to Mr. Alexander Hellard, town clerk, by 3 p.m. on 27th inst. Form of tender must include a declaration that the person making the tender pays not less than the trade union rate of wages, and observes the hours of labour and conditions recognised and in practice obtained by the trade unionists in the borough.

Islington.—The Vestry are open to receive tenders for the wiring of the Vestry Hall and municipal offices in Upper-street, N., and for the supply of fittings. Specification, etc., can be obtained on application to the electrical engineer, Electricity Department, 50, Eden-grove, Holloway, N. Deposit of £1. 1s. will be required for the forms, but such deposit will be returned on receipt of a *bonâ fide* tender. The contractor whose tender is accepted will be required to pay his employés engaged on the work the trades' union rate of wages and observe trades' union conditions and hours of labour. He will also be required to enter into a contract and to find two sureties for the due execution of the work. Tenders must be sent in by 27th inst.

Wakefield.—The Corporation invite tenders for the supply and erection of the following: Section A—boiler-house plant (boilers and fittings, mechanical stokers and engine economiser, feed-pump, injector, etc.); Section B—engine-house plant (steam alternators, condensers, oil filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tank, etc.); Section C—main switchboard and instruments; Section D—underground work

Digitized by Google

(cables, junction-boxes, culverts, and trenching, etc.); Section E—sub-station fittings (transformers and switchboard, etc.); Section F—arc lamps and posts; Section G—meters; and Section H—overhead crane. Particulars are obtainable from Mr. Robert Hammond, Ormond House, Great Trinity-lane, E.C., on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders are to be delivered by August 24 (to-morrow).

Queenstown (Ireland).—Tenders are invited by the Queenstown Town Commissioners for the lighting of Queenstown by electricity (private as well as public) as per report and specification of Mr. R. Hammond, M.I.E.E., Ormond House, London. Tenders are also invited as follows: the contractor to provide the capital for the due erection of the works and maintenance thereof as per above plans and specifications, on being guaranteed the public lighting, and a stipulated number of private lights (to be agreed upon), the Commissioners having the right to purchase within a specified period. Plans and specifications are deposited at the Hall, Queenstown, and can be inspected there between 11 and 2. Tenders must be lodged with the town clerk, Queenstown, marked "Tender for Electric Lighting," by 2 p.m. on September 16. Further particulars and conditions to be had on application to Mr. James Ahern, town clerk, Queenstown.

RESULTS OF TENDERS.

York.—The City Council have been recommended by one of their committees to accept the tender (£8,650) of the Electric Construction Company for the supply of the first instalment of electric lighting plant.

Ilford.—The Council have accepted the tender of the Consolidated Telephone Construction and Maintenance Company, Limited, at £5 per annum for five years, for the provision of telephonic communication between the residences of the officers of the fire brigade, the stables, and the police station.

Lancaster.—Messrs. Drake and Gorham have been successful in obtaining the contract for the electric lighting of the Lancaster Infirmary with about 250 lights. The committee have also decided to place with the firm the work in connection with the electrical cooking, telephones, bells, speaking-tubes, and medical switchboards.

Walsall.—The Town Council have approved of the borough offices being lighted electrically, and that the tender of Messrs. Fallows and Wheatcroft be accepted for supplying and fixing the necessary fittings for the sum of £62. 10s. The tender of the Walsall Electrical Company, Limited, at £139. 5s. 6d., has been accepted by the Town Council for wiring, supplying, and fixing 82 incandescent lamps at the Town Hall.

Brighton.—The following tenders have been received by the Corporation for the supply and erection at the electricity works, North-road, of evaporative brass-tube surface condensers, electrically-driven air-pumps, exhaust and condenser piping:

Wright's Patent Heater Condenser Company, Westminster (accepted)	£2,476
E. Larsen, 19, Eastcheap, London	2,900
J. Fraser and Son, Millwall Boiler Works, London, E.	3,460

Bradford.—The following tenders have been accepted for the supply of best gas coal, cobbles, nuts, and cannel, for one or two years, commencing August 1, for the Gas and Electricity Supply Committee: J. Brown and Co., Limited, Atlas Works, Sheffield; Newton, Chambers, and Co., Limited, Thorncliffe Collieries, near Sheffield; Strafford Collieries Company, Limited, Barnsley; H. Briggs, Son, and Co., Limited, Whitwood Collieries, Normanton; Pope and Pearson, Limited, West Riding and Silkstone Collieries, Normanton; Locke and Co., St. John's Colliery, Normanton; Stanley Coal Company, Limited, Stanley Colliery, Liversedge; Barrow Hematite Steel Company, Limited, Barrow Collieries, Barnsley; West Yorkshire Iron and Coal Company, Limited, Leeds; Park Coal Company, Limited, Liversedge, *vid* Normanton; E. T. Ingham, Thornhill Collieries, Dewsbury; Liversedge Coal Company, Liversedge, *vid* Normanton; Mirfield Coal Company, Ravensthorpe, near Dewsbury; Lofthouse Colliery, Limited, near Wakefield; Crosland Coal Company, Limited, Scholes, Cleckheaton; W. Ackroyd and Bros., Limited, Morley Main Collieries, Morley; H. Ellison, Cleckheaton; J. and J. Charlesworth, Limited, Milnes House, Wakefield; Crawshaw and Warburton, Ridings Colliery, Dewsbury; Soothill Wood Colliery Company, Limited, Soothill Wood Colliery, Batley.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,753.

Midhurst (Sussex).—At a parish meeting a suggestion has been made that the electric light should be adopted.

House-Lighting.—The Tayler Smith Electric Company have been instructed to instal the electric light at 45, Ennismore-gardens, for Mrs. Goldsmid.

West India and Panama Telegraph Company.—The receipts for the half month ended August 15 were £1,649, as against £1,638 for the corresponding period.

The Brush Company.—The Brush Electrical Engineering Company, Limited, give notice that the debenture stock transfer-books of the Company will be closed till September 3.

Theatre-Lighting.—The Royalty Theatre, Dean-street, Soho, which has been closed for some time, will be re-opened early next month. In the interim the electric light has been introduced.

Brazil.—The Municipality of Itapecerica, Sao Paulo, propose to light that town by means of electricity, and have invited Dr. O'Connell Jersey, engineer, to submit plans and estimates for this purpose.

Donegal.—The Government have entered into negotiations for the purchase of the telegraph cable laid some years ago by Lloyd's Committee between Tory Island and the mainland of Donegal.

Mechanical Traction Syndicate, Limited.—This Company has been registered by H. Willett, 9, St. James's-square, Manchester, with a capital of £21,000, to construct and maintain any tramways or light railways.

Manufacturing Rights.—Messrs. Easton, Anderson, and Goolden, Limited, inform us that they have secured the sole rights for the manufacture of the "Niagara" crusher and pulveriser (W. H. Coward's patent).

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 18th inst. amounted to £1,374, as compared with £1,126 in the corresponding week of last year, being an increase of £248.

General Trades and Industrial Exhibition Company, Limited. This Company has been registered by John Dale and Co., Limited, Bridge-street, Bradford, with a capital of £5,000, to acquire the business of a promoter of exhibitions, etc., as hitherto carried on by E. Cox, of Birmingham, and to develop and extend the same.

City and South London Railway.—The returns for the week ended August 18 were £924, compared with £861 for the corresponding period of 1894, being an increase of £63. The total receipts for the half-year 1895 are £6,008, as compared with £6,063 for the corresponding period of 1894, being a decrease of £55.

Inyati Syndicate, Limited.—This Company has been registered by Cheston and Sons, 7, Great Winchester-street, E.C., with a capital of £15,000, to acquire any concessions or grants of land, mining, or other rights, etc., to construct and maintain rail or tram roads, or other public works, in Africa or elsewhere, and to turn to account the same.

Aberdeen.—On Monday evening one of the two new steam-engines, each of 200 h.p., which have been obtained in connection with the extension of electric lighting in Aberdeen, was turned on at the station in Cotton-street. Councillor Johnston, convener of the Gas and Electric Lighting Committee, was present, and switched on the dynamo. The engine, which worked very smoothly, and gave every satisfaction, was used to generate the current required during the evening.

Sunderland.—A report has been drawn up by the Highways Committee of the Sunderland Corporation with regard to the cost entailed by the introduction of the electric light into the town. It shows that up to June 30 the amount expended over the scheme was £20,961, and that there was further expenditure anticipated, bringing up the total to £22,987. 11s. 5d. It also shows that there has been a loss on the present year's working of £700. The committee have agreed to advise the Council to increase the electrical engineer's salary by £60 per annum.

Christchurch.—At a committee meeting of the whole Council Mr. Burt attended and explained a method for lighting the town by electricity. It was resolved, on the proposition of Alderman Druitt, seconded by Councillor Marshall, that the committee thank Mr. Burt for bringing the subject before the notice of the Council, and for the information he had given them. It was also unanimously resolved, on the proposition of Alderman Druitt, seconded by Councillor Green, "that the subject is one which deserves the closest attention of the Council, and that they consider the subject in the future, when further information has been obtained."

Leytonstone.—A meeting of the Wanstead Slip Ratepayers' Association has been held, Mr. W. Boddy presiding. The meeting protested against the decision of the Leyton District Council to introduce the electric light into the district; they did not require it. Mr. Boddy said the question of electric lighting had been before them some years. He believed the lighting of the public lamps, etc., cost the Council £3,000 a year at present, and it had been said that to instal the electric light in Leyton would cost £60,000, and that light would cost 50 per cent. more than gas. It was decided to send a deputation to wait upon the Leyton Urban Council on this and other matters.

Harbertonford.—Messrs. Churchward and Son's serge factory at Harbertonford was on Friday evening lighted by electricity. The installation was carried out by Mr. A. F. Lord, electrical engineer, Totnes, and a large company was invited to witness the switching on of the current. Two large switches control the dynamo and lamps These were manipulated by Mrs. Churchward and Mrs. Hoare, wives of the heads of the firm. The dynamo was manufactured by Messrs. Newton, of Taunton, and worked the 140 lamps with complete satisfaction. After the light had been turned on the company inspected the factory, and were unanimous in praise of the steadiness and purity of the light.

London County Council Loans.—The London County Council having reduced from 3¼ to 2¾ per cent. their rate of interest on loans to local authorities exceeding £10,000, the St. Pancras Vestry have agreed to borrow from the Council the sum of £75,000 for electric lighting and other purposes. The money is to be repaid in 42 years by 84 equal half-yearly instalments of principal and interest combined. By the reduction in the rate of interest the parish will save £8,396. The Vestry have received a cheque on account of the loan for £56,100, and the balance will be

Digitized by Google

forthcoming when the officers of the Council have reported on the works for which the remainder of the loan is required.

Liverpool.—At the annual meeting of the Liverpool United Gaslight Company, which was held on Tuesday, Mr. Edward Lawrence, the chairman, said that the Corporation had lately taken a new start. They had purchased the electric lighting company, and therefore they might expect in due course that, so far as the Corporation was concerned, gas would be superseded by electric light, but he was very doubtful whether the Corporation would be able to persuade the public to take the more expensive illuminant any better than the electric lighting company had done. At all events, he could see nothing to make them feel that the property of the gas company was not as good as it had always been,

Electric Train Staff System.—The new electric train staff system has been successfully inaugurated on the Dungannon and Cookstown branch of the Great Northern Railway of Ireland, and the intervening sections between the Coalisland and Stewartstown Stations. By the new mode it is impossible for more than one train to be on a section at the same time, and this positively prevents collisions, as a train cannot enter a section until it is signalled clear from the next station, and the staff automatically given. The instruments, which are very intricate, were put up in the various cabins by Mr. Morris, the Government linesman, and at first trial worked without a hitch. The new system, which is also in operation from Dundalk to Derry and from Portadown to Omagh, will be extended to the Armagh and Newry branch.

Removal.—Messrs. Crompton and Co. are removing their electric heating department from 148, Brompton-road to Cornwall-buildings, 35, Queen Victoria-street, E.C. This step is necessitated by the increase of business and the desirability of being in a more accessible position for enquirers, who come from all parts of the country and abroad to see these new applications of electricity. The Brompton-road showrooms have answered the purpose of introducing electrically heated apparatus to the public and showing the possibility of its use, and after three years' experience the department has been placed on a permanent footing. From this date all enquiries should be sent to the new address, where Mr. H. J. Dowsing will be pleased to afford any information as to the various applications of electric heating. The showroom at Brompton-road will be kept open by the Kensington and Knightsbridge Electric Light Company for the benefit of their customers who may wish to see various applications of electricity.

Weybridge.—An adjourned public meeting on the lighting question has been held, at which Mr. Young moved, "That it is the opinion of this meeting of ratepayers of Weybridge that the lighting of the parish should be in the hands of the Urban Council." The Chairman asked whether Mr. Young meant to convey by his resolution that they should take over the electric lighting works, or that the matter should be left to the Urban Council to settle. Mr. Young said he meant that the works should be purchased. Mr. Palmer, who seconded Mr. Young's resolution, said he did not understand that that was the construction to be placed upon it. If it was in order he should move an amendment that that meeting of ratepayers, having confidence in their Council, should refer the whole question of the lighting of the district to their decision. The chairman accepted the amendment, which was then seconded by Mr. Benson, and carried. This closed the proceedings, and the decision of the question is still left to the Urban Council.

Bath.—At Monday's meeting of the Surveying Committee of the Town Council the report of the electric light inspector for the fortnight stated that experiments had been carried on by the manager as to the practical difference shown in the illumination by using different brands of carbon some of which were much superior to the rest. Those used on Saturday and Sunday nights produced a very fluctuating light, and it was probably due to this cause that five lamps were extinguished on Sunday night and one on Saturday night. There was a discussion on the character of the electric lighting, and Alderman Taylor moved that the electric lighting company be requested to give the illuminating power they had contracted to supply to the authority and discontinue explanations such as that sent on this and other occasions. Mr. Knight suggested that Alderman Taylor might put in the gas company. Alderman Taylor said no, because he was afraid they would go to the strict terms of their contract and supply 14-c p. lights instead of 16·32 c.p. The Chairman pointed out that the report was an explanation of their own officer. Alderman Taylor said it was not the kind of thing they wanted. The Chairman suggested that he should round off the corners of the motion a little, and Alderman Taylor then suggested that the clerk should be asked to write to the company that they did not want any more experiments at their expense. Mr. Mitchell, however, seconded the first proposal, which was carried unanimously.

Rhyl.—As the Rhyl Urban District Council felt in a difficulty as to giving consent to the construction of a tramway in Rhyl, it was decided to call a meeting of ratepayers and property owners. This gathering was held on Tuesday evening. Captain E. W. Keatinge, chairman of the Council, presided, and the Town Clerk explained that of three applications sent in for power to construct a tramway that of Mr. Chadwell, of Blackburn, had been recommended by the Road Committee of the Council for acceptance, gas being the motive power. Mr. T. C. Amos proposed that the meeting approve of the scheme, and adopt a system of tramways for Rhyl. Mr. Coxhead seconded, but objected to any system such as overhead electric wires, as the desire of Rhyl people was to clear away all obstructions on the promenade. Councillor Jos. Williams, amid some interruption, opposed the scheme as being dangerous to the large number of children who visited Rhyl. Mr. Lewis Jones questioned the chairman as to whether the Council had ascertained the cost of making and working the line, as Rhyl people did not want any more financial failures. Mr. Cheetham said that if the town adopted any system at all it should be one worked by electricity, and above all they should keep private companies out of the field. He proposed that the system be an electric one. Mr J. Morris seconded. Councillors P. Mostyn Williams and Elwy Williams, and the Rev. T. Shankland spoke against any tramway scheme, upon the ground that Rhyl was a pleasure resort, and the streets were too narrow and the distance too short from place to place; also that it would lower the tone of Rhyl, besides being dangerous to pedestrians. Mr. Abel Jones moved that the meeting should be adjourned in order that the lodging-house keepers, who were busy, might attend, and this was carried by a majority.

The Snaefell Electric Railway.—On Friday last Colonel Rich, of the Board of Trade, and Major Cardew inspected, on behalf of the Manx Government, the new Snaefell electric railway. The line extends a distance of 4¾ miles, with a continuous gradient of 1 in 12, from Laxey to the summit of Snaefell—over 2,000ft. above the sea-level. It is substantially constructed with solid embankments and heavy steel rails. There is a centre rail on which emergency grip brakes, which have been specially devised for the line, act. The inspectors carefully examined the line and the electrical equipment of the cars, and travelled in a car the whole length of the line and back. In descending the steepest incline at full speed the special emergency brakes were applied, with the remarkable result that the car, which was weighted to represent an ordinary load of passengers, was brought to a complete standstill in its own length. The retaining walls and embankments were examined by Major Cardew, and the engines and dynamos at the generating and accumulating stations were also inspected. Their exhaustive examination being finished, the inspectors expressed themselves as highly satisfied, and said they would report to the Lieutenant-Governor that the line was in perfect order for passenger traffic. At lunch afterwards, Mr. Hopkinson, of Manchester, proposed success to the undertaking, and Mr. A. Bruce, chairman of the company, responded. The engineers (Messrs. McKerrow and Fell) were present, as was Dr. Edward Hopkinson, on behalf of Messrs. Mather and Platt, who constructed the electrical plant. The whole line was built in six months, and all the overhead conductors were erected in 10 days. The line was opened for public traffic on Tuesday. There is now complete electrical communication between Douglas and the top of Snaefell—a distance of 12 miles. The Ramsey Licensing Court have by dint of Puritan influence declined to grant a seven days' license for the new hotel at the top of Snaefell. They have, however, managed to be so far judicious in granting a license for six days.]

Newport (Mon.).—The installation of the Town Hall at Newport with electricity has now been practically completed and the current switched on to the wires. A test was made on Monday night, in the presence of Alderman Moses, Alderman T. Jones, and Councillor G. Greenland, members of the Electric Lighting Committee, and those gentlemen, together with a few visitors, were all satisfied in the highest degree with the measure of success attained. The wiring and fitting of the building has been carried out by the Electric Installation Company, of Westminster, whose contract was £517, exclusive of some portion of the fittings. Every room, office, floor, and corridor has been connected, about seven miles of wire having been utilised in the work. The wires are doubled, so that if fuses go in any room, only one-half of the lights in the particular room will go out. The Council-chamber and the assembly-room have been most handsomely and artistically fitted. In all there are 425 lights throughout the establishment, including those in the police quarters, cells, etc. The turret clock was lit on Saturday by the new supply with 24 lights, there being six 16-c.p. lamps to illuminate each of the four dials. The work throughout reflects the greatest credit on the company with whom the contract was placed, and their foreman, Mr. Rixom. Almost all the places in the town connected are now supplied with the current. There has, unfortunately, been some delay with the new engines locally supplied for driving what is known as the night load—the heaviest load of all. The engines, so far, have not been got to govern quite as nicely as is desirable. Under the circumstances, and whilst the necessary alteration are being made to adjust the governors properly, the Corporation decided to get a set of small plant from the Messrs. Fowler, of Leeds, which was quickly placed in position, and is now running very smoothly. The arc lamps for street-lighting will, it is hoped, soon be placed up, and when the big engines have been got to govern properly, the town—or the central portions—will be lit by the new illuminant.

Taunton.—Mr. Harold W. Cousens, the electrical engineer to the Town Council, has reported to them that during the past quarter he had removed all the overhead wires in North Town and North-street, and that the underground cable had worked very satisfactorily, giving a uniformly high insulation resistance. He was carrying out the improvements and extensions recommended by Dr. Fleming in his last report, and the switchboard, ordered last month from Messrs. Newton, was in course of manufacture, and they were pushing on well with the work. It would, when erected, greatly aid in the efficient handling of the circuits. The lamp load was steadily increasing, as shown from the fact that they had added 73 16-c.p. lamps to the mains during the past quarter. The report of the Electric Lighting Committee was presented as follows: "Your committee have ordered that a cable be laid through the Crescent, as recommended by Dr. Fleming. Your committee herewith present the contract with Mr. Newton for supplying and fixing the switchboard, and they recommend that

Digitized by Google

the common seal of the borough be affixed thereto. Your committee recommend that tenders be obtained for 1,000 tons of best Powell Duffryn coal, to be delivered as ordered from about December 1 next." Councillor Webber was surprised that such a little-used locality as the Crescent should be lighted by electricity, but he supposed it was owing to the fact that several members of the committee lived there. Councillor Potter replied that the committee were assured that certain residents would very probably take in the light if it was laid along the street. Alderman Stanfast thought the committee were going a little too fast, as he was surprised to find these extensions so rapidly carried out. If they were not careful, all the £3,000 just sanctioned would be spent in a very short time. He also complained of the uncertain character of the street lamps. He noticed that Bath-place was to receive attention, and he supposed it was to light up the darksome Conservative Club there. The report was adopted. The Finance Committee presented a number of accounts which they recommended for payment, including £888. 17s. 11d. on the electric light account, and £56. 8s. 1d. on the electric light loan account. The accounts were passed.

Harrow.—A special meeting of the District Council has been held, at which the clerk submitted a letter from the Board of Trade, dated August 2, forwarding for any observations the Council might wish to make a copy of a memorial they had received from certain ratepayers at Harrow, with reference to the proposed transfer of the Harrow Electric Lighting Order to the Harrow Electric Light and Power Company, Limited. It was moved by Dr. Williams and seconded by Mr. Hawkins that the Council make the following observations upon the memorial: "With regard to Clauses 5, 6, and 7 of the memorial, the new Urban District Council at its second meeting refused by five votes to four to pass a resolution interfering with the transfer of the provisional order. The clerk to the Council did not become solicitor to the company until after the resolution of January 14, in favour of the transfer to Messrs. Crompton and Hawtayne, was carried. His advice on the matter was not asked. The notice signed by Messrs. Crompton and Hawtayne was brought before the Council on July 8, 1895, and it was decided by five votes to two (two members not voting) to give directions to advertise and deposit the draft deed of transfer and submit to the Board of Trade for their approval With regard to paragraph 11, the draft deed of the transfer has already been submitted to the Council, and considered by them on two occasions—viz., at meetings on January 14 and July 8. With regard to the suggested additions to the draft deed, it appears to the Council that (*a*) is met by paragraph 17 of the draft deed of transfer, which precludes any subsequent transfer of the provisional order, except in the case of charges by the Council. It appears to the Council that (*b*) is met by Section 1 of the Electric Lighting Act of 1888, which enacts 'the grant of authority to any undertakers to supply electricity within any area where granted by license or by means of a provisional order to the local authority, or to any other company or person within the same area.' That copies of resolutions passed at the meetings of January 14 and July 8, 1895, be forwarded to the Board of Trade." On the motion being put, the chairman, Dr. Williams, and Mr. Hawkins voted for it, and Messrs. Clowes and Strange against it. It was therefore declared to be carried.

Canterbury.—At the last meeting of the Town Council Alderman Mason, in accordance with notice of motion, brought forward the subject of the electric light. He remarked that, seeing the previous negotiations had failed, and seeing the miserably inadequate light with which the city had recently been supplied, the time had now come when the Council should take some steps to acquire the electric light for the benefit of the citizens. He did not see why the matter should be shelved The Council had already gone to the expense of £400 to obtain their provisional order, and he thought they should now take some further steps in the matter. At some places the electric light was provided by the public authorities themselves with considerable benefit to the ratepayers, and he should be sorry to see Canterbury behindhand in this respect. He begged to move an instruction to the committee to consider the advisability of again advertising for the supply of electric light or taking steps to supply it themselves. Councillor Horsley seconded the motion. He quite agreed that the lighting of the city was not a credit to it. Without committing themselves to the form in which the light should be provided, he thought they should issue early instructions to the committee to proceed in the matter so that at an early Council meeting they might decide whether or not they were going to make use of the provisional order. Personally, he believed it was quite possible to work it by the power they already had. Replying to Councillor Harris, the Town Clerk said the negotiations with the Brush Company were at an end. By the order the Council could themselves undertake the lighting, or transfer their power to another company for a consideration. Alderman Hart said he did not quite see why Alderman Mason should censure the gas company, who would give the Council as much light as they liked if they would pay for it. With reference to the quality of the light, he reminded the Council that it was in their power at any time to test it. At the present time they supplied the city with from 14 c.p. to 16 c p At least, that was the report the directors had from their gas manager. As to electricity, he had not one word to say against that, as the Council were quite right to go forward, but he did not think the gas company should be censured. Alderman Sanderson said the quality of the gas on some occasions might be equal to that Alderman Hart had mentioned, but he must assert that they did not usually get what they wished to pay for, nor did they get a proper pressure. He quite endorsed what Alderman Mason had said. The time had come when they should seriously consider the matter. The Mayor thought it only right to mention that the citizens were very much indebted to the company for their liberality in illuminating the Westgate Towers so successfully during cricket week. The resolution was carried.

Electric Light at Brompton Hospital.—In the treatment of that terrible and mysterious disease, consumption, no precaution against contamination of air can be considered too great. If there is one thing more necessary for the consumptive patient than another it is, perhaps, that the air which he or she breathes should be absolutely pure Recognising this fact, the *City Press* says, the committee of the Brompton Hospital for Consumption and Diseases of the Chest have recently decided, after much deliberation, to light the whole of the hospital by electricity It is a bold step for a large hospital, mainly dependent upon voluntary contributions, to take, inasmuch as the cost of the installation, to say nothing of the increased expense of lighting, is very considerable. But the committee of the institution have come to the conclusion that the outlay is amply justified, bearing in mind the terrible nature of the disease which they have to cope with. If not the first, it is one of the first of the great London hospitals to adopt the electric lighting system, and there cannot be the least doubt that the change will conduce to the general welfare of the patients, who number upwards of 300. The hospital chapel has for some years past been lighted with electricity, the electric power being supplied by the House-to-House Electric Light Supply Company. Limited But now that it has been decided to light the hospital throughout in this manner the committee will provide their own installation Messrs. Laing, Wharton, and Down are the contractors, and it is expected that the installation—the work in connection with which has already been commenced—will be completed in about three months. The machinery is being fixed in the rear of the new extension buildings, and it will comprise a dynamo capable of running at 145 volts, a large battery of accumulators, and one of Messrs. Crossley's gas-engines. The lamps to be used are of the small incandescent type, and there will be 1 209 in all. There are some seventy wards to be lighted, together with the nurses' dormitories, the doctors' bedrooms an entertainment hall, and the administrative and other offices. The cost of lighting will, of course, be slightly higher, but the benefit derived by the patients will be considerable, and the committee and supporters of the institution are to be congratulated on the excellent example they have set. The hospital is the largest of its kind in the kingdom. The parent hospital has accommodation for 210 in-patients; and a large extension building, on the opposite side of the Fulham-road, providing 137 additional beds, was opened in 1882. The new building contains a spacious out-patients' department, and is fitted with every modern appliance which can conduce to the well-being and comfort of the inmates. Having in view the heavy outlay which this important extension has involved, as well as the serious increase in the annual expenses consequent on the occupation of the new building, the committee invite liberal aid by means of new subscriptions, donations, and legacies.

Brighton.—At the last meeting of the Town Council the Lighting Committee reported that they had had before them the following tenders for the supply and erection of exhaust-pipes, valves, etc, at the electricity generating station: Messrs. J. Fraser and Son, Millwall, £594; Messrs. Reed and Son, Brighton, £540; Mr J. Every, Lewes, £494 10s; Mr. H North, Brighton, £489; and resolved that the tender of Mr. H North be accepted. A letter from Councillor Dunk complaining of the inefficient lighting of Hanover-terrace was referred to the borough surveyor to report upon. With regard to tenders for the supply of condensers, etc., for the Corporation electricity works from Messrs. J. Fraser and Son, Millwall, £3 460; Mr. E. Larsen, 18, Eastcheap, London, £2,900; and Wright's Patent Heater Condenser Company, Westminster, £2,476, it was resolved that the tender of Wright's Patent Heater Condenser Company for the supply of evaporative brass tube surface condensers, electrically-driven air-pumps, and exhaust and condenser piping be accepted. Councillor Stafford having moved these proceedings, Councillor Greenyer asked whether, in putting up the standards for the electric light extensions on the east front, it would be necessary to disturb the asphalte again, and whether it would not have been better to have erected them when the cables were put in. Councillor Dell congratulated the committee upon having determined to give the town something for its money by erecting electric lamps in the Western road. He, however, asked whether the committee could not have done something towards illuminating the triumphal arch put up in the Queen's-road in connection with the Foresters' visit to Brighton; he supposed it was possible for the committee to put in the electric light for any such erection within 24 hours. Alderman Abbey said remonstrances had been made to him as to what the committee were doing on the Parade, and he assured the Council the greater number of the residents in the eastern portion of the town were in favour of the present improved system of gas illumination being retained. The argument he, however, had employed in response to those who had complained to him on the subject was that the cost of the electric light would be something about half the price of the gas now used, and he wished now to know from the chairman of the committee whether there was anything in that argument. Councillor Stafford, in reply to Councillor Greenyer, said they would, of course, have to disturb the asphalte in fixing the standards on the Parade, but if he went along the Western road he would see how expeditiously the work was being done there As to the remarks of Councillor Dell, they could, if necessary, connect the electric light to a building in the space of two hours; while, with respect to Alder-

Digitized by Google

man Abbey's observations, although the cost of electricity might not be less by half than that of gas, it would undoubtedly be lower, and there would be an increase in the illumination. He was also sure that, as the result, the Marine-parade would be so beautifully lighted that when it was done the alderman would come to the Council and thank the committee.

Harrogate.—The Town Council have held a meeting at which the report of the General Purposes, Plans, etc., Committee was read. It ran: "(1) Electric Lighting Sub-Committee's report: The Electric Lighting Sub-Committee reported that they met on July 4: (*a*) as to Mr. Hammond's report—Mr. Hammond's report having been printed and sent to each member of the Council, the committee read through and considered the same, and it was resolved that the town clerk arrange with Mr. Hammond to attend a meeting of the General Purposes Committee at an early date to go through and explain certain portions of his report, and that Mr. Wilkinson be invited to attend the same meeting; (*b*) as to cables: resolved, that the British Insulated Wire Company be asked to supply cables for the low-tension system, in addition to the tender already accepted; resolved, that the report be approved and adopted. (2) Electric lighting: Mr. Hammond, consulting engineer, and Mr. Wilkinson attended the committee, and after reading Mr. Hammond's printed report they advised the committee thereon. (3) Turbines: resolved, that Parson's system of steam turbines be not adopted, but that a slow-speed flywheel alternator plant be adopted. (4) Boilers: resolved, that two Lancashire boilers, 30ft. by 8ft., be purchased. (5) Cables and conduit: resolved, that a double cable be adoptod and a 6in. conduit be laid to the gate leading to the farm. (6) Site of generating works: resolved, that the near site, that is on the north side of Oakbeck, as shown upon the plan, be adopted for the generating works. (7) Small plant: resolved, that a small daylight plant be also provided. (8) Junctions and meters: resolved, that in the first instance the sum of £800 be spent in providing junction-boxes and meters to 100 customers. (9) Revised specifications: resolved, that Mr. Wilkinson prepare a revised specification upon the basis of Mr. Hammond's report, incorporating the foregoing resolutions passed by the committee to-day." The Mayor moved the confirmation of the minutes. Alderman Hammond seconded, and the motion was carried. Councillor Scholes reported that along with Councillor Simpson he had visited the fire-tanks. Respecting the fire brigade and salvage corps bells the manager (Mr. Beaumont) said he had had considerable difficulty lately, not only with the fire brigade bells, but the electrical apparatus altogether. He said he had put on a stronger generator, and would try that for a time, and if not satisfactory then he would divide it into three separate circuits, and then he would guarantee it would be right. Since the generator had been put on the bells had rung satisfactorily. The Mayor remarked that it had been found that since the salvage corps had been connected the bells had not worked very well. A more satisfactory way to do would be not to mix up the two, but have two separate batteries. Councillor Scholes remarked that to do that they would have to duplicate the whole system. After further remarks the Mayor suggested that both matters be referred to the committee, and on the motion of Alderman Hammond, seconded by Councillor Hartley, this course was agreed to.

Yarmouth.—A meeting of the Town Council has been held at which the surveyor's monthly report on electric lighting stated that the expenditure for July amounted to £114. 11s. 5d., and the income to £102. 6s 8d., showing a loss of £12. 4s. 9d. The total loss on working for the half-year to June 30, as shown by the monthly reports, had been £164, but in consequence of an insufficient sum having been apportioned to the street-lighting, that was reduced somewhat; and after making allowances for some small items omitted from the expenditure account, the loss on the first six months' working might be definitely placed at £130, to which should be added the repayment of capital and interest. The mains in Broad and Market rows, Regent-street, and Market-place were now working up to their full load. That was not injuring cables, but might inconvenience customers. Some of the transformers were also fully loaded. He therefore advised that extensions of the mains provided for in the last loan should be proceeded with at once. It would take nearly three months to manufacture the large cables, which should be brought up from the central station by Southgates-road and South Quay to the Town Hall, and thence to some central point near the south end of the market, where a large transformer and sub-station should be put in so as to supplement the present cables, which were likely to be overloaded. There should also be some additional low-tension mains put in so as to reinforce the present low-tension network. He recommended that tenders be obtained for the cables and transformers, but that the work of trenching, laying, and making good should be performed by men in the employ of the Corporation. The arc lamps on St. Peter's-road being at work, he recommended that the gas lamps which they were intended to displace should be discontinued. He considered it desirable that a coal contract should be entered into which should extend over the winter up to midsummer of next year, by which time it was probable that the new coal stores would be ready to take in a much larger stock than could be accommodated at present. Ten meters were needed; cost, £45. The Electric Lighting Committee instructed the surveyor to consult with Mr. Preece as to the new mains suggested in his report, resolved to recommend the Council to have tenders obtained for the cables and transformers required, and instructed the borough surveyor to give notice to the gas company that the lamps in St Peter's-road would not be required after half-quarter day; to obtain tenders for supply of coal for the ensuing 10 months; and to purchase the meters asked for in his report. The surveyor estimated that the 11 lamps at the Fish Wharf would be alight about 800 hours during the ensuing season, and the cost would be about £50. Since the last meeting of the committee the customers had applied for 421 lamps, increasing the total number of customers to 99, for 5,122 lamps. A memorial from residents in Jubilee-place, Market-road South, for more light was referred to the Lamp Committee. Mr. H. Calver asked, by letter, that the gas lamp at the north end of Wellington-road might be allowed to remain, as the electric light at the corner of Napoleon-place did not illuminate the corner where the former was. The Sanitary Committee decided this matter should stand over.

The Rise in Copper.—During the last fortnight, the *Financial News* said on Saturday, the price of copper has risen about £1. 7s. 6d. per ton, and Chili bars were quoted yesterday at £46. 12s. 6d. per ton for cash and £47 per ton for three months forward delivery. Those who are usually best informed speak very confidently of a further rise in the metal, and the statistics appear to confirm their view. Both in June and July there were unusually large exports from the United States, and if the shipments from that quarter were to continue on the same scale we could scarcely expect that the visible supply of copper would remain within its present limits, and with the increase in the stock the price would naturally decline. But our information has been to the effect that the American exports would not be so large after the end of July, and the result of the first half of August bears it out. In June the arrivals of American copper at European ports amounted to 6,073 tons, and in July to 7,740 tons; but for the first 15 days of August they only reached 2,070 tons. If the arrivals during the latter half of August are not on a considerably larger scale, it is obvious that the month's supplies from the United States will be only slightly over 4,000 tons. And it seems more than probable that for some time to come the monthly supplies will not exceed this figure; for consumption has lately shown a great increase in the States, and we have it on the authority of the Government Geological Survey that no notable new discoveries of copper deposits were made last year, and that there were no indications of any sudden expansion of the producing capacity. The importance of the United States in the copper situation will be realised when we state that the world's total supply in 1894 was 319,391 tons, of which North America produced 175,290 tons. Assuming the Government report to be correct in saying that there are no indications of a sudden expansion in the country's producing capacity, and bearing in mind the increase in consumption that was noticeable in Europe last year, and has now extended to the States, the copper shipments from North America become a matter of the greatest interest. In 1894 the arrivals in Europe from the United States amounted to 71,480 tons, and in 1893 to 77,414 tons—far larger quantities than had ever been exported before. The extraordinary depression in both those years in the States probably accounted for the great increase in the shipments, and it is one of the best features in the situation that Europe was able to absorb so much American copper. It is generally believed that in normal times the United States could not spare more than 40,000 tons a year, at most, for export, and if we go back for a few years we find that the exports of American copper in 1892 were only 29,000 tons, in 1891 34,500 tons, in 1890 22,000 tons, and in 1889 32,000 tons. Now, if in the dull times of 1894 and the previous year Europe was able to take the large quantities of American copper that we have mentioned, it is a fair presumption, with a consensus of opinion that trade is improving, that Europe will want in 1895 at least as much copper as it did last year. Unless the United States can supply it, we do not know where the necessary quantity will be obtained, and, according to the July circular of one of the leading metal brokers of New York, the "large quantities due on contracts to American consumers will necessitate keeping the more copper here"—that is, in the States. There, thus seems to be good reason for believing that the stocks in Europe will not be supplied to the same extent as formerly by American copper, and as the deliveries during the first half of this month exceeded the supplies by 1,152 tons, a further rise in copper appears to be almost certain. It comes to this, that the only country from which we can draw supplies of unknown quantity is North America, and if she wants the metal for home consumption, and will not export it, we shall see the inevitable result, when the demand is greater than the supply, of higher prices; and we need hardly add that no company will profit more by the rise in copper than the Rio Tinto.

Ipswich.—A meeting of the Paving and Lighting Committee of the Town Council was held on Friday last, when the Town Clerk said some misapprehension existed as to what had been done by the County of London and Brush Provisional Electric Lighting Company. Mr. Paris called upon him and stated that he was sorry the application of the company for the approval by the Corporation of their application for a provisional order had not been considered. He (the town clerk) told Mr. Paris that the Corporation had not received any application for their approval, and after going into the matter Mr. Paris admitted that this was so. Both the secretary to the company and Mr. Paris had written on the assumption that the application had been made, whilst as a matter of fact it had not been made. All that he (the town clerk) had received had been the registered letter giving notice of intention to make the application. However, the company had plenty of time in which to take the next step. Mr. Paris said he assumed that he (the town clerk) would take his first application as the application for the assent of the Corporation, but his reply naturally was that if the company wanted the assent of the Corporation they must follow the proper form of application. He had received a letter from the engineer and manager of the

Digitized by Google

company, Mr. A. J. Lawson, who wrote: "Mr. Paris has asked me to place officially before you the financial position of this company so that the same can be considered at the next meeting when the question of our application for a provisional order for Ipswich comes before the Municipal Council. The company was registered in 1891 as 'The County of London Electric Light Company,' and the name was changed in June, 1893, to the present name, but no capital was subscribed, with the exception of £1,000, until the beginning of 1895, when we issued a prospectus inviting applications for £200,000, all of which was taken up. In February of the present year a further issue was made of £130,000, so that at the present time the amount of capital subscribed is £330,000. Under our articles of association the company is empowered to issue £400,000 ordinary shares, £400,000 preference, and £400,000 in debentures, while among our largest shareholders are some of the most influential and important members of our banking and mercantile community of London. Our chairman is the Right Hon. D. R. Plunket, Q.C., M.P." The letter went on to state that the company practically own the whole of the shares in the Bournemouth, Richmond (Surrey), and Dover Electric Companies, and are interested in the Windermere and Scottish House-to-House Companies. Besides they are carrying out work in their own name in the London districts of St. Luke and Clerkenwell and Wandsworth. Mr. Lawson trusted the information would be sufficient to show that should the Council consent to the application for a provisional order they were dealing with a company amply able to carry the undertaking to a successful issue. The Town Clerk added that still the company did not make their formal application for the assent of the Corporation. He did not see that the information assisted the Corporation much, inasmuch as the company did not state what their liabilities were in respect to the undertakings they had mentioned, or what capital would be alloted to the Ipswich undertaking. He understood that the desire of the Council was to have the control of electric lighting in their own hands, and if anyone applied for an order they would oppose it. Mr. Pratt: At the same time, I don't think we can stand by and keep others out unless we show that our intention is really to proceed. Mr. Josselyn said he was inclined to think it would be better that electricity should be supplied by a private company. Mr. Churchman: I should like to see someone else burn their fingers over it. Mr. Josselyn said at all events it was not a matter for their committee to decide. It must come before the Council when the company made their application for approval. The matter then dropped.

The Copper Market.—Messrs James Lewis and Son, in their mid-monthly report on copper, write: Copper of all kinds has been in active request during the past fortnight, and a large business has been done in good merchantable, the price of which last week receded from £46. 5s. to £45. 1s. 3d. under pressure of the realisation of a considerable quantity bought during the excitement of three months ago and now falling due. On the conclusion of these sales values quickly reacted and have steadily advanced, until they close to-day (17th) at £46. 10s. for cash and £46. 17s. 6d. for three months, buyers, the advance since the 1st inst. being 15s. per ton. Three hundred and twenty-five tons of American bars and ingots have been shipped from here to New York, and further 200 tons follow. Several hundred tons of electrolytic copper have been sold back to the United States, and a quantity of Orford ingots are being returned from Havre. We hear also that English best selected has been sold for shipment thither; so long as prices with us keep below the parity of those ruling in New York we may expect these shipments to continue, and they will soon materially diminish the stocks held in Europe. In New York the price of Lake copper has advanced to 12 25 cents per pound. It is estimated that about 10,000 tons of various kinds of copper were sold during the month of July to American consumers for delivery during the last four months of the year. As a number of the smelting furnaces at Anaconda are being pulled down and rebuilt, the production of this company will fall off materially for some time. Out of 13 588 miles of street railroad existing in the United States, 10,363 miles are worked by electricity. Producers' returns are as follow:

	July.		Jan. to July.	
	1895.	1894.	1895.	1894.
European production	6,988	6,960	49,472	52,218
American production	12,524	12,639	83,136	86,590
,, imports	1,100	1,340	10,200	9,380
,, exports*	6,036	7,225	39,350	46,994

	Tons.
*United Kingdom	644
France	993
Germany, Holland, etc.	4,397
Mexico	2
	6,036

American exports for the first half of July are 1,910 tons. Stocks have decreased 752 tons, and the visible supply 1,271 tons during the past fortnight. Imports to date are 894 tons, and deliveries 3,601 tons greater than last year. The arrivals in England and France for the fortnight have been 3,657 tons, and the deliveries 4,409 tons. The arrivals of Chile in Liverpool and Swansea have been 900 tons and the deliveries 626 tons, and from other countries 2,011 and 2,527 tons fine respectively. The arrivals here and in Swansea from the United States have been 124 tons bars, seven tons ingots, and 80 tons matte, equal to about 171 tons fine, and in France 210 tons fine. The Chile charters for the past fortnight are advised as 1,000 tons, and exchange 17⅜d.

Stocks of Copper (tons fine)—	June 1. 1895.	July 1. 1895.	Aug. 1. 1895.	Aug. 16. 1895.

Worcester.—At the last meeting of the City Council, in submitting the report of the Electricity Committee, the Deputy-Mayor (Mr. G. H. Williamson) said it had come to his knowledge that a report was current in the city that he was, or had been, in some way interested in the British Electric Installation Company. If it were the fact that he was connected with any installation company in the city and at the same time occupied the chair of the Electricity Committee, he would be occupying a position which he was not at all entitled to—it would be very unfair and dishonourable. As a matter of fact, he had never had any interest whatever in that or any other electricity company either in Worcester or out of it at any time. He had neither lent them money nor supported them in any way. He did not know how the report had got so widely circulated, but he thought it his duty to take that opportunity of contradicting it. His work on the committee during the last 18 months had given him far more anxiety than his own business, or anything else he had been connected with, and he thought it quite enough to have that anxiety without having unfair reports circulated behind his back. Mr. Bozward remarked that they all agreed that Mr. Williamson was a gentleman of the highest honour and integrity, and that he would do nothing to compromise himself or the city. Mr. Williamson moved, and Alderman Ernest Day seconded, the adoption of a recommendation for the purchase of two water-meters for testing the evaporative power of the coal used at the generating station, at a cost, including fixing, of £33. In reply to Mr. Lewis, Mr. Williamson said such meters were used all over the country, and he believed they could be relied upon. Mr. Lewis: I am given to understand there is not a meter in existence that can be relied upon. The recommendation was adopted. The Council also agreed to a recommendation of the committee to accept the tender of Messrs Haynes Bros. for the construction of a pit for the weighing-machine at the generating station at £34. 15s. The committee recommended that the electrical engineer should be authorised to grant to each workman in his department one week's holiday per annum. In moving the adoption of the recommendation, the Deputy-Mayor said the stokers, engine-drivers, etc., at the generating station got one Sunday out of three. In order to do this on another Sunday they worked eight hours, and the other Sunday 16. The men did not have any Bank Holidays, and apart from one Sunday in three, they had no holidays at all. Their work was very close and arduous; the men had to be extremely careful what they were doing, and they could hardly expect them to keep in health if they had no opportunity of recruiting themselves. The Corporation paid the drivers the minimum trades union rate of wages—32s. a week—and they worked rather more than the usual number of hours. Some of the labourers worked as many as 84 hours per week. The proposal would cost £15 or £16, and he thought the money would be well spent. Mr. Chaplin seconded, remarking that the system proposed was adopted throughout the country, and he thought it would be an incentive to the workmen to do their work in the best possible manner. Mr. Lewis said there were men who had been employed at the cemetery from 10 to 20 years who had never had a day's holiday. Instead of only giving one class of men a holiday, they should consider whether the whole of the Corporation labourers should have it. The Sheriff supported the proposition, but sympathised with Mr. Lewis's suggestion that the whole subject should be considered. Mr. Winwood thought the whole matter should be referred back to the committee. The Corpora-

Digitized by Google

tion wagoners had to be at work at six in the morning, and could not leave before six in the evening, and had no holiday except one day in the year when they went into the country. Mr. Lewis proposed, and Mr. Barnett seconded, that the matter should be referred back to the committee. Mr. Williamson said the adoption of the recommendation would give the workmen heart, and show that the Corporation sympathised with them. The workmen had a lot of very valuable property in their care, and any negligence on their part might cost the city hundreds of pounds. The amendment was lost, and the recommendation of the committee adopted.

PROVISIONAL PATENTS, 1895.

AUGUST 12.

15121. **An improvement in secondary batteries.** William Henry Willatt, 22, Jalland-street, Holderness-road, Hull.

15134. **Improvements in apparatus for covering electrical and other wires.** Charles William Washington, Market-place, Huddersfield.

15166. **Improvements in electrophores applicable as electric lighters.** Jean Henri Peletan and Edouard Christophe, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, 13th February, 1895, being date of application in France.

15174. **Improvements in single-phase and multiphase alternate-current motors.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

AUGUST 13.

15178. **Improvements in electric arc lamps.** Edward Jesse Piper, 34, Victoria-street, Westminster.

15215. **Improvements in and pertaining to telegraphic and other printing apparatus.** Charles Luman Buckingham, 46, Lincoln's-inn-fields, London. (Complete specification.)

15216. **Improvements in electric lighting attachments for gas-burners.** Frank Alden Webb, 18, Buckingham-street, Strand, London. (Complete specification.)

15225. **Improvements in electric brakes.** James Devonshire 70, Chancery-lane, London. (William B. Potter, United States.) (Complete specification.)

AUGUST 14.

15259. **Improvements in and connected with dynamo-electric machinery.** Montague Sabor Pickstone, 4, Corporation-street, Manchester.

15260. **Improvements in electromagnetic separators.** Frederick George Robinson, 10, St. George's-crescent, Liverpool.

15276. **Improvements in self-recording electric meters.** Edwin Percival Allam, 49, Finsbury-pavement, London.

15288. **Improvements in electric clocks.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Société Anonyme La Précision, Belgium.)

15292. **Improvements in galvanic batteries.** Henry Tipping and John Blomfield Hamond, 19, Gloucester-place, Greenwich, London.

15295. **Improvements in the manufacture of illuminating bodies for use in electric lighting.** Emil Joseph Constam and Leon Gaster, 46, Lincoln's-inn-fields, London

15301. **Improvements in electric exploders.** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

AUGUST 15.

15338. **Improvements in electric arc lamps.** Rowland Hill Barnett, Akenside-hill, Newcastle-on-Tyne.

15343. **Improvements in couplings or joints for the sheathing of electrical conductors.** Hugo Hirst, 73, St. Stephen's-road, Upton Park, London.

15363. **Improvements in electrical distribution.** Charles Ernest Spagnoletti, The Poplars, Aberdeen-place, London.

15365. **Improvements in and relating to electric switches.** William Henry Dingle and John Mackenzie Urquhart, 23, Bucklersbury, London. (Complete specification.)

15369. **Improvements in secondary or storage batteries.** Joseph Baxeres Torres, 17, St. Anne's-court, Wardour-street, London.

15371. **Improvements in and connected with primary batteries.** Walter Rowbotham, 45, Southampton-buildings, Chancery-lane, London.

AUGUST 16.

15431. **Improved electric apparatus for striking bells and the like or giving signals.** Denys Mathieu, 27, Martin's-lane, Cannon-street, London.

15432. **Improvements in or relating to batteries.** Denys Mathieu, 27, Martin's-lane, Cannon-street, London.

15433. **Improved electric apparatus for striking bells and the like or giving signals.** Denys Mathieu, 27, Martin's-lane, Cannon-street, London.

15442. **Improved means for supporting or suspending electroliers and the like, and for facilitating the raising and lowering of the same.** Harold Faraday, 11, Southampton-buildings, Chancery-lane, London.

15445. **Improvements in step-by-step printing telegraphs.** Walter Samuel Steljes, 24, Southampton-buildings, Chancery-lane, London.

15450. **Improvements in electric telegraphs.** Secondo Roos, Ferdinando Luraschi, and Ettore Luraschi, 45, Southampton-buildings, Chancery-lane, London.

15461. **Improvements in or relating to telephone receivers.** Stephen Henry Snowden, 37, Chancery-lane, London.

15470. **Improvements in asynchronous electrical machines.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France.)

15471. **Apparatus for converting alternating electrical currents into continuous currents.** Godfrey Bamberg, 28, Southampton-buildings, Chancery-lane, London.

AUGUST 17.

15511. **An improved hand-feed projector arc lamp.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

15513. **Automatic regulator for dynamo-electric machines supplying electric motors.** Alexander Donay, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1891.

11473. **Electromagnetic motors.** Lake. (Tesla.) (Second edition.)

1894.

14113. **Electric meters.** Cooper and others.

16916 **Lime and electric lights.** Taylor.

17378. **Direct-current transformers.** Blackburn and Boyden.

18177. **Electrically-actuated brakes, etc.** Auguste-Godchaux.

18196. **Electric conductors.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

18273. **Electric motors.** Imray. (Société Anonyme pour la Transmission de la Force par l'Electricité.)

21838. **Electrolysing chemical combinations, etc.** Bein.

1895.

9708. **Electric heaters.** Delany.

12229. **Electric resistances.** Voigt and Haeffner.

12420. **Electric battery plates.** Weise.

NOTES.

Train-Lighting.—Electric lighting for railway carriages, which has for some time been in use on a few of the leading Russian railways, is now, it is said, to be adopted for the express and mail trains on them all.

Industrial Premiums.—The Italian Minister of Agriculture and Commerce offers for competition, up to December 31, 1895, a large number of medals and diplomas for various industrial and art work, including an electrical long-distance power-transmission plant.

Incandescent Lamps.—Among the novelties in electric incandescent lamps is a lamp with a mirror placed inside the globe. The mirror throws the light out from the base in the direction the light is required. An inventor of Florence, Italy, is the originator of this novelty.

Motors for Horseless Carriages.—In answer to Mr. Macdona, Mr. Chaplin has stated in the House of Commons that the subject of motors for horseless carriages is one to which his attention has been drawn, and it is his intention to carefully consider it in connection with the Bill which was introduced last session by his predecessor.

Books Received.—We have received a copy of a treatise on "Experiments with a New Polarising Photo-Chronograph Applied to the Measurement of the Velocity of Projectiles," by Dr. A. C. Crehore and Dr. G. O. Squier (Artillery School Press, Fort Monroe, Virginia, U.S.A.); and the "Programme of Technological Examinations" held under the auspices of the City and Guilds of London Institute (Whittaker and Co., 10d.).

The Americans Again.—Weeds along railway tracks in the United States are now said to be killed by the "electric weed killer." It consists of a car carrying a dynamo, which sends a heavy current into a sort of rake of fine wires dragging among the weeds on each side of the track. As the wires touch them the weeds are "electrocuted" down to their smallest rootlets. It is proposed to introduce the same system in farming.

Telegraphy in Russia.—Vice-Consul Cooke, of Archangel, reports to the Foreign Office that the existing telegraph lines from Archangel to Kem are to be continued all along the White Sea littoral and the Murman to Vadsö and Vardö. The wires now in course of erection from Mezen to Ust-tsilma, the centre of administration of the Petchoro districts, will thus in another way bring the great outlying regions in touch with Archangel and with the world.

The Companies' Acts.—Sir Albert Rollit on Tuesday asked in the House of Commons whether the Government intended to adopt the draft Bill suggested by the Companies' Act (Amendment) Committee appointed by the Board of Trade with a view to securing early legislation on the subject. Mr. Ritchie replied that the whole matter was under his careful consideration, and he felt sure his hon. friend would see that it was impossible for him to make any announcement at present.

The Telephone Service.—On Tuesday in the House of Commons, Mr. Hanbury, in reply to Mr. M. Healy, said that, without expressing any opinion on the subject at present, the Government would carry out the recommendation of the late committee by reappointing a committee next session to consider and report upon the evidence already given on the conditions of the telephone service and the terms of the license between the National Telephone Committee and the Post Office Department.

The New Brussels Electric Tramcar is attracting a good deal of attention in Belgium. It is of such a size that the Brussels people call its type mastodonic. It is of open construction, has nine transverse rows of seats, with a total accommodation for 50 people; is run by its own dynamos; and is curved at both ends in order to avoid fouling at tangents. The Compagnie des Tramways Bruxellois is responsible for the introduction of the new car, which is claimed to be the first of its kind in Europe.

North-East Coast Institution.—Part IX. of vol. xi. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders to hand contains Mr. Henry Foster's reply to the discussion on his paper, "On the Application of the Electric Arc to Machinery and Boiler Repairs, etc."; the adjourned discussion on Mr. S. O. Kendall's paper on "Turret-Deck Cargo Steamers," and Mr. Kendall's reply; and the adjourned discussion on Mr. G. H. Baines's paper on "The Metric System of Weights and Measures," etc., and Mr. Baines's reply.

Copper in New South Wales.—The copper lodes in New South Wales were first opened in 1858, since which time many thousands of tons of copper ore have been obtained. The cupriferous district covers an area equal to about 4,296,320 acres; but there are enormous tracts of country the exploration of which will increase the area. The most important copper mine in the colony at the present time is the Great Cobar Mine, and it is also the most distant from the seaboard, being 497 miles west of Sydney. The value of the copper raised in the colony and exported to the end of 1894 was £6,343,044.

Electricity in Convents.—Electricity is getting on in Italy. The Sacra Congregazione dei Vescovi, of Rome, having been consulted as to the propriety of installing the telephone in a convent, has replied that there might be no objection to the introduction of the instrument provided that it be used solely in "grave circumstances," and that two sisters are present during the communication. And with regard to the electric light, the same sacerdotal body is of the opinion that it may also be employed except at very important religious ceremonies, when candles only must be utilised. So says the Milan journal *L'Elettricità*.

Berlin Industrial Exhibition.—The German Consul-General has issued a copy of the programme of the industrial exhibition to be held in Berlin from May to October next year, of which Prince Friedrich Leopold of Prussia is the patron and Baron von Berlepsch, the Prussian Minister of Commerce, the honorary president. The exhibition will comprise 24 groups, among them being those for textile industries, clothing, building and engineering, wood, china and glass, metals, chemicals, food products, scientific and musical instruments, electricity, paper industries, leather, photography, education, fishing, shipping, and horticulture.

Queen's College, Ireland.—In the House of Commons on Saturday, speaking on the report of the vote for the Irish Board of Works buildings, Mr. Dillon said, with regard to the Queen's College, that there was an item in the vote of £2,500 for a chemical laboratory in Belfast. He did not object to that, but he thought it was unfair, considering that Galway received only £150, and Cork received nothing, although a laboratory was badly needed in the latter college. Mr. Hanbury, in reply, said that it was true that there was a charge for Belfast Queen's College, but none for Galway or Cork. That only applied to the present year. He had the figures relating to the total cost of the Queen's College.

Foreign Gas Journals.—The editor of the *Journal de l'Eclairage au Gaz*, commenting on the report of the electric

Digitized by Google

lighting of Brussels, points out how poor the result is. Here is a station working to its full capacity and it can only make 3·64 per cent. to meet interest and sinking fund, while there is not a word about depreciation. The local conditions are all favourable, and yet this is all. The gas undertaking at the same time makes 8·2 per cent. on a capital of £720,000. The Geneva station has no dividend to declare, although it is worked entirely by water and pays no tax to the Municipality. The only way of making electricity pay, adds the editor, seems to be by running small local stations. He does not draw any inferences from the short time the electric works has been in operation, or from the fact that the gas consumption is not on the increase in Brussels.

The London and Paris Telephone.—On Tuesday last Mr. Henniker Heaton asked the Secretary to the Treasury, as representing the Postmaster-General, whether he could state the annual revenue and expenditure in connection with the telephone service between London and Paris; whether the telephone was used only or almost exclusively in business hours, and was idle for 16 hours out of the 24; and whether he could see his way to reduce the rate for three minutes' conversation. Mr. Hanbury said that the Postmaster-General regretted that he was not in a position to give the information asked for in the first paragraph, and the use of the telephone was by no means restricted to what were commonly called the business hours of the day. The rate was a subject of international agreement and the Postmaster-General did not see his way at present to propose any reduction.

An Aerial Railway. — Among the most recent projects for rapid transit is one by which the cars are suspended, and the motive power is electricity. As the centre of gravity is very low, derailment in this form of aerial railway is practically impossible. A road built on this plan has been designed by Herr Langen for Berlin and other places in Germany. A foreign journal says: "The system is adopted for ordinary rapid transit or high-speed service, it being claimed that a speed of 186 miles per hour can be attained. Friction plates prevent the derailment of the wheels, and they are secured to the motor case in the usual manner, the shocks being taken up by springs. The car is fastened to the motor in such a way by a centre pin as to permit of lateral play, and is suspended by springs, ensuring easy riding. Each truck has four wheels, and is provided with brakes, which take hold of the rail at top and bottom. Each car has two motors and seats 50 people."

Thermo-chemical Carbon Battery.—M. Korda, in *Compt. Rend.*, states that experiments made with a view to ascertain whether in the reduction of metallic oxides there is a development of electrical energy, show that only in two of the cases investigated is there any distinct E.M.F. Barium peroxide in contact with carbon heated at dull redness gives an E.M.F. of about one volt. Other peroxides, such as those of manganese and lead, show no similar behaviour, probably because the product of reduction is a conductor and forms short-circuits with the carbon. Copper peroxide and carbon, when separated by fused potassium carbonate, give an E.M.F. of 0·9 to 1·1 volt. If the potassium carbonate contains water, the current is at first in the opposite direction, but changes as the temperature rises. In both cases the E.M.F. is considerably lower than that calculated from the known thermal disturbances, and it follows that only part of the energy is liberated as electrical energy. Faraday's law is not applicable, because of the continuous supply of extraneous energy in the form of heat.

Electric Tramways in Germany. — The three members of the Berlin City Council who visited fourteen great European towns in order to examine the arrangements made for dealing with the traffic, recommend the underground conduit system of electric traction for the busier streets of the capital and the overhead conductor system for the less important thoroughfares and for those subject to floods. They also report that the transition from the overhead to the underground system can easily be effected when necessary; and, in contradistinction to some other opinions, that the Klette underground method of traction, as tentatively employed in Dresden, is a good one. A project for the construction of an electric railway from Brunswick (Braunschweig) to Wolfenbüttel has, furthermore, been presented to the authorities concerned. The Allgemeine overhead conductor system would be used; the line would be double-tracked to Richmond, thence single-tracked, and the 11 motors with their cars would attain a speed of from 12 to 15 English miles an hour. A peculiarity of the cars is that their seats would be removable to enable merchandise to be carried.

Belting.—The manufacture of electrical apparatus and the development of allied interests, have brought about many interesting changes of late years. In England the progress of the industry has been aided by and has aided the production of high-speed engines. In America, on the other hand, most of the dynamos have been belt-driven. In conjunction with this, what is said to be the largest belt in the world is that just furnished by the Jewell Belting Company. This belt is 118ft. long, 78in. wide, and four ply, and weighs considerably more than a ton and a half. It is now in use at a wire factory in Worcester, Mass., where the increased demand for electric wire has necessitated an increase in the power plant. The belt will be called upon, when running its full load, to transmit 2,000 h.p. It will be used to run nine mills, comprising at least two-thirds of the power consumed in the works. This belt has now been in use over a month, and is running as true and steady as an ordinary narrow single belt. It is worth noting that on the same day on which the Jewell Company received the order for this 78in. belt it also received an order for five 62in. three-ply belts for the Cincinnati Street Railway Company. If this is an average order in America, we shall expect our belt manufacturers to become strong opponents to high-speed engines.

Oskar von Miller on Overhead Conductors.—The well-known German electrical engineer, Herr Oskar von Miller, has recently given his opinion on the overhead-conductor system of electric tramways, especially in regard to its application in Nuremberg. According to the *Elektrotechnischer Anzeiger* of August 8, he concludes his remarks as follows: "It is my opinion that the Nuremberg Tramway Company is scarcely bound at present to introduce the working by accumulators or underground conduits in all streets, but the numerous improvements which may soon be expected in both systems will probably result in many cases in the discontinuance of the use of overhead conductors, while the possibility of doing away altogether with them is not very remote. I should therefore recommend that the Nuremberg Tramway Company be allowed, in the first place, to use overhead conductors in all streets, but that the clause which binds the company, on the expiry of six years, to remove the overhead conductors, when, in the opinion of a Court of Law, a new system of motive power, without overhead wires, has demonstrated its excellence, both from an electrical and viatectural point of view, be amended in that the tramway company will have, in the more important thoroughfares,

Digitized by Google

within a fixed period, and without a decision of a Court of Law, to discontinue the use of overhead conductors."

The Proposed Derbyshire Electric Railway.—Further particulars are published regarding the light electric railway which it is proposed to construct between Derby and Ashbourne. Mr. John Shaw, jun., of Derby, with the assistance of Messrs. Dickinson, of Birmingham, well known in connection with the South Staffordshire Electric Railway, has prepared a scheme for the construction of this light railway, and the proposal has already met with much favour, alike from the landowners, farmers, and others in the district. The prime cost of the railway equipped in the ordinary way was estimated at from £30,000 to £50,000 per mile. Consequently, such a railway running from Derby to Ashbourne would cost from £600,000 to £800,000, whereas to build and work a light electric railway on the overhead electric system has been amply proved to be the cheapest and most suitable method in the case of the Derby and Ashbourne line. The cost of running per car mile by the overhead system, including all expenses, with the exception of guards' wages and maintenance of permanent way, is estimated at 4·06d., compared with 8·57d. by steam. It is proposed that the line should be connected with the existing Derby tramway, which terminates on the Ashbourne-road, and thence it would run through the parishes of Mackworth, Kirk Langley, Brailsford, Ednaston, Osmaston, Compton, into the town of Ashbourne, terminating near Compton Bridge.

Electrocution of Shade Trees.—It is a question, says the *Chicago Record*, whether the stringing of electric wires in cities and villages will not destroy a large proportion of the shade trees. Complaint is made in several cities that where the wires pass through the foliage the trees in nearly every instance have died, presumably from the effects of the electric current. It has been noticed also that the death of the trees almost invariably follows a season of rain, when the wet leaves are good conductors of electricity and carry it from the wires to the trees. In some cases the death of trees has been caused by wires supposed to be thoroughly insulated, the covering having been rubbed off the wires by the friction of the branches when moved by the wind. The evidence that the trees have been killed by electricity is furnished by the fact that in numberless instances the trees through which the wires pass died in an hour during a storm, while those standing a few feet from the wires were uninjured. These results will raise the question as to the liability of electric light companies for the damage caused by the killing of shade trees. The right to string electric wires does not give the further right to destroy the shade trees, which may constitute the chief value of a piece of real estate. Neither does it give the right to lop off the branches and otherwise disfigure ornamental trees simply because such branches happen to be in the way of the wires. This has been done by an electric light company in one of our suburban villages, and many large and beautiful trees have been practically ruined by such vandalism.

British Association Ipswich Meeting. — The following is the probable programme of Section G.: Thursday, 12th—Address by President, Prof. Vernon Harcourt, M.I.C.E.; Light Railways in Agricultural Districts, Major-General Webber; Congelation of Soil for Foundation Purposes, M. Gobert (a Belgian engineer); Bentley Coal Borings (a local work), R. C. Rapier. Friday, 13th—The Growth of the Port of Harwich, W. Birt (general manager, Great Eastern Railway); Notes on Improvement of Mass in Connection with Hook of Holland Route, the President; Snowdon Tramroad, Sir Douglas Fox; Notes on Autumn Floods of 1894, W. H. Symons; River Weirs and Flood Prevention, F. G. M. Stoney (designer of Richmond Weir). Saturday, 14th—Dredging Operations at Mersey Bar, A. G. Lyster, M.I.C.E.; Carbonic Anhydride Refrigerating Machinery, E. Hesketh (of Hall and Co., Dartford); Deodorising Sewage by Hermite Process at Ipswich, F. Napier (borough analyst). Monday, 16th, electrical day—Induction Telegraphy, Notes on Further Advance, W. H. Preece; Glow Lamps, W. H. Preece; Modern Applications of Electricity to Traction, P. Dawson; The Chloride Battery, W. H. Earle; Extension and Development of the Telephone in Agricultural Districts, Major-General Webber; Telephony, A. R. Bennett; The Field Telegraph in the Chitral Campaign, P. V. Luke (Deputy Director of Telegraphs in India); A New Portable Photometer, W. H. Power and A. E. Trotter. Tuesday, 17th—Interim Report of Committee on Standardising; Modern Flour-Milling Machinery, F. W. Turner; Paper-making Machinery, Mr. Mason; Printing without use of Movable Types, J. Southward; Incandescent Gas Lamps, C. Cooke; B.A. Standard Small Screws, R. B. Crompton; Uniform Factor of Safety in Steam-boilers, J. Key.

Fatality.—"A shocking accident, which resulted in the death of a young man, named Waller, aged 23, a native of Blackburn, Lancashire, occurred on Monday on the electric tramway at Bushmills. It appears that he and another young man were coming from Belfast around the coast to Portrush on bicycles, and when about a few hundred yards beyond the tramway station on the Portrush road, it is believed that the deceased, endeavouring to run his bicycle on to the tram line, struck the elevated kerbing of granite, about 5in. in height, which at this place divides the county road from the tram line, and was pitched over the machine on to the elevated rail, which was then charged with electricity. His companion, who was a few yards in advance, hearing the deceased shout, returned to his assistance, and found him lying on the rail and his bicycle on the top of him, and also in connection with the rails, thus probably causing a double current of electricity to pass through the body of the deceased. In trying to release the body from the rails the deceased's companion had a severe shock, owing to the ground rail and clothing of the deceased being wet. The unfortunate young man was immediately removed to the waiting-room at the station, where, despite the efforts of two doctors, he expired shortly afterwards." We have taken the report of this sad accident from the account given by the *Daily Telegraph*. It is exceedingly difficult to understand how such a fatal accident could have happened. Having passed over the line on Saturday and Sunday last, we have the details of construction fairly in mind. The rails form the return circuit and the current is taken from a rail about 18in. above the ground. The voltage does not usually, we were informed, exceed 300 volts, so that one could hardly have expected such an accident.

Epoch-Making Inventions. — An American subscriber, at present in Paris, writes to us that he is pained to see that we have located the good Ananias as an inhabitant of the great American Republic. He, as evidence of the good faith of American journalists, sends us an item from the *New York Mail*, observing that as this is an age of unbelievers there will very likely be found some readers who will question its accuracy, but at the same time it is entertaining. The paragraph runs: "Dr. Denkla M. Squilmuth, ex-supervisor of the poorhouse at Malvern, L.I., has at his farm, near Dendy's Station, a remarkable herd of shorthorn Jerseys. For three summers past he has lost several by lightning, and this year four were killed during June. He now has each

Digitized by Google

cow fitted out with a small lightning rod and a storage battery, and, while none has been killed, so great is the amount of electricity secured that the batteries provide all the power needed to run the doctor's six big churns, the daily product of which is over one thousand pounds of butter." But, after all, Glasgow is turning up as an opponent of the States. Some newspaper man there has wired to various papers (and had accepted) the following astounding information: "Two Glasgow gentlemen have just taken out provisional patents for an invention which, it is claimed, will mark an epoch in the mining history of the world, and more particularly Western Australia. The invention is pneumatic in character, and will do away with water power for working the stamps, substituting a combination of electricity and air. The Western Australian Government are interested in the invention, and the Rothschilds are understood to be desirous of launching the company, provided they get certain controlling powers. The capital will be the largest of any company this century."

Regulation of Dynamos Driven by Fixed Expansion Steam-Engines.—M. F. Mélotte recently made a communication to the Association des Ingénieurs-Electriciens de Montefiore in which he stated that he had found that in order to increase the voltage of a shunt dynamo driven by a fixed expansion engine it is in certain cases necessary not to augment, but to diminish the excitation. Take the instance, he says, of a steam-engine the governor of which acts only on the valve. It is ascertained, for example, that at a little below full load the engine does not attain its normal speed, and that the voltage as well as the output of the dynamo are very small. The steam entering, the energy per piston-stroke is maximum, and the power furnished by the engine is proportional to the speed. If, with the object of increasing the voltage, the excitation be augmented, this is what follows: the load of the steam-engine increases; the engine slackens, but the power of the dynamo diminishes more rapidly than the speed, while that of the steam-engine decreases proportionally to this speed; so that a state of equilibrium is attained at a speed lower than the primary speed. At the same time the voltage has naturally declined, so that in increasing the excitation you have run counter to the desired object. If, on the other hand, the excitation be diminished, the load inclines to decrease, and the engine gains in speed and yields a proportionately greater power; but with the speed the load of the dynamo augments more rapidly than that of the motor, whence a new state of equilibrium at higher speed and voltage. This method of regulation ceases to be efficacious when, the proper speed being obtained, the governor begins to act; then a fresh diminution of the excitation would cause a decrease of the magnetic field which would no longer be compensated by an increase of speed, and the voltage would diminish. In a case quoted by the author, with an engine of 300 h.p., at 350 revolutions a minute, which, with full excitation, only made 315 revolutions and supplied 115 volts, the speed has been caused to rise to 350 revolutions and the voltage to 125 with full load by diminishing the excitation. M. Mélotte has observed the same incident of regulation in the driving of a dynamo by a gas-engine.

Then and Now.—The late Sir William Siemens in 1877, in an address before the Iron and Steel Institute, said: "The advantage of utilising water power applies, however, chiefly to continental countries, with large elevated plateaus, such as Sweden and the United States of America, and it is interesting to contemplate the magnitude of power which is now for the most part lost, but which may be, sooner or later, called into requisition. Take the Falls of Niagara as a familiar example. The amount of water passing over this fall has been estimated at 100,000,000 tons per hour, and its perpendicular descent may be taken at 150ft., without counting the rapids, which represent a further fall of 100ft., making a total of 300ft. between lake and lake. But the force represented by the principal fall alone amounts to 6,800,000 h.p., an amount which, if it had to be produced by steam, would necessitate an expenditure of not less than millions of tons of coal per day. It would not be very difficult, indeed, to realise a large portion of the power so wasted by means of turbines and waterwheels erected on the shores of the deep river below the falls, supplying them from races out along the edges. But it would be impossible to utilise the power on the spot, the district being devoid of mineral wealth or other natural inducements for the establishment of factories. In order to render available the force of falling water at this and hundreds of other places similarly situated, we must devise a practical means of transporting the power. As regards electrical transmission, suppose water power be employed to give motion to a dynamo-electric machine, a very powerful electrical current will be the result, which may be carried to a great distance through a large metallic conductor, and then be made to impart motion to electro-magnetic engines, to ignite the carbon points of electric lamps or to effect the separation of metals from their combinations. A copper rod 3in. in diameter would be capable of transmitting 1,000 h.p. a distance of, say, 30 miles—an amount sufficient to supply 250,000 c.p., which would suffice to illuminate a moderately sized town." What he then talked of as being merely within the range of possibilities is to-day an accomplished fact. It is on record that his audience received the statements made with an incredulous smile.

A Cable for St. Helena.—St. Helena is one of our possessions with which we have no telegraphic communication. The subject is dealt with by a writer in the *St. Helena Guardian*, who says: "Some years ago Mr. Haliburton wrote about the defenceless state of St. Helena, and in his most able letter he points out the want of a cable from the Imperial side of the question. In this matter Imperial and island interests are one. Without a cable St. Helena, and I might add Ascension, are worse than valueless to the Empire, seeing that these would be, in war time, a constant source of anxiety, the Home authorities not knowing whether these islands were captured, besieged, or what not. With a cable the island could be used as a base for cruisers to operate from with a view of protecting the Cape route to the East, and a large stock of coal would no doubt be kept for cruisers making the island their headquarters. This much for the Imperial advantages of having the wire laid down. From the islanders' point of view, I do not hesitate to say that a cable would benefit every man, woman, and child in the place, and more than double the value of property in St. Helena. Of the scores of ships which now pass without calling at least two-thirds would call for orders; there is no better situated place anywhere than St. Helena for getting orders at for sailing vessels. I have little doubt that the regular mail steamers to the Cape would also stay here for a brief period if once the cable was established to communicate with England and the Cape. Men-of-war would, instead of remaining a few days, and having to run up to Sierra Leone if they wished to communicate with the admiral, stop here for weeks and perhaps months at a stretch, provided the Nanas and Kokos on the coast were quiet. I need not dwell on the advantages of men-of-war

Digitized by Google

being in port; they are apparent to all. The many schemes for resuscitating St. Helena I think all hinge on the cable; freights would fall owing to more ships visiting the place, at present they are sufficiently high to kill any export trade that might be started. Finally, from a speculator's point of view, I feel sure the St. Helena cable would pay the investor. Ships would use it to inform their owners of their arrival and to get orders where they were to go to discharge. The Colonial Office would use it to send instructions from time to time to the Governor, the War Office would use it in connection with the garrison, the Admiral and the Admiralty would use it for the men-of-war and troopships calling here. Private individuals and business men would use it, and the steamship companies would, with the passengers, wire home reporting their arrival and departures."

Professional Ethics.—The following code of ethics has been adopted by the Boston Society of Architects as a guide to its members. Although some of the statements show somewhat of the trade union spirit, we should be pleased to know that all our consulting engineers were prepared to abide by the spirit of this code in future. The code reads as follows: No member should enter into partnership, in any form or degree, with any builder, contractor, or manufacturer. A member having any ownership in any building material, device, or invention proposed to be used on work for which he is architect, should inform his employer of the fact of such ownership. No member should be a party to a building contract except as "owner." No member should guarantee an estimate or contract by personal bond. It is unprofessional to offer drawings or other services on approval and without adequate pecuniary compensation. It is unprofessional to advertise in any other way than by a notice giving name, address, profession, and office hours, and special branch (if such) of practice. It is unprofessional to make alterations of a building designed by another architect, within 10 years of its completion, without ascertaining that the owner refuses to employ the original designer, or, in event of the property having changed hands, without due notice to the said designer. It is unprofessional to attempt to supplant an architect after definite steps have been taken toward his employment. It is unprofessional for a member to criticise in the public prints the professional conduct or work of another architect except over his own name or under the authority of a professional journal. It is unprofessional to furnish designs in competition for private work or for public work, unless for proper compensation, and unless a competent professional adviser is employed to draw up the "conditions" and assist in the award. No member should submit drawings except as an original contributor in any duly instituted competition, or attempt to secure any work for which such a competition remains undecided. The A.I.A. "schedule of charges" represents minimum rates for full, faithful, and competent service. It is the duty of every architect to charge higher rates whenever the demand for his services will justify the increase, rather than to accept work to which he cannot give proper personal attention. No member shall compete in amount of commission or offer to work for less than another, in order to secure the work. It is unprofessional to enter into competition with or to consult with an architect who has been dishonourably expelled from the "institute" or "society." The assumption of the title of "architect" should be held to mean that the bearer has the professional knowledge and natural ability needed for the proper invention, illustration, and supervision of all building operations which he may undertake. A member should so conduct his practice as to forward the cause of professional education and render all possible help to juniors, draughtsmen, and students.

Institution of Junior Engineers.—The Belgian summer meeting of this institution, which took place last week, passed off very successfully. Assembling at Harwich, the party, consisting of nearly 60 members, crossed by the Great Eastern Railway's ss. "Ipswich," and arrived at Antwerp on Saturday morning, the 17th inst. Here they were welcomed by M. Royers, engineer-in-chief to the Municipality, who conducted them over the extensive docks, and explained the numerous features of interest in connection therewith. The Musée Plantin and the station of the Compagnie Hydro-Electrique Anversoise were also specially open for inspection. On Monday the members proceeded to Ghent, where MM. Carel's engine works, M. Van Houtte's nursery gardens, and M. de Hemptinne's cotton-spinning mills were seen, the respective proprietors showing the visitors round. In the evening Brussels was reached, and the central electric light station there was visited under the guidance of Mr. Phibbs. Tuesday was left open so as to afford the opportunity of visiting the various places of popular interest for which the city of Brussels is noted; in the afternoon, most of the party made an excursion to the field of Waterloo. Leaving Brussels on Wednesday morning, the members arrived at Liège about noon, and were received by M. Gillon, president of the Association of Engineers from the University of Liège, and by M. Firkets, president of the Liège section. The afternoon was devoted to visits to the Vieille Montagne Zincworks at Angleur, under the direction of M. Gillard, secretary of the company, and other gentlemen; and the St. Leonard Locomotive Works, where the chief engineer, M. Shoest, showed the members over. In the evening, at the Hôtel de Suède, a banquet was given in honour of the institution by the Liège section of the Association of Engineers from the University, M. Gillon presiding, faced by M. Firkets. On Thursday an excursion was made to Verviers, on the invitation of the Chamber of Commerce. Arriving at Est Station, the president, M. Garot, M. Mullendorff, M. Soubre (secretary), and other gentlemen of the town, met the members, and entering carriages drove to the wool-washing, combing, and dyeing works of MM. Peltzer et Fils. The wool-card manufactory of M. Duesberg-Debrez was next visited, after which the party were entertained at luncheon at the Société de l'Harmonie, M. Garot presiding. The wool-spinning, weaving, and finishing works of MM. Peltzer were seen afterwards, and train was then taken for visiting, under the guidance of the engineer, M. Mahwood, the Gileppe reservoir, which supplies water to Verviers and Liège. In the evening the Liège electric lighting station was seen, Mr. Hickson conducting the members through it. Friday's programme comprised a visit to the extensive works of the celebrated Cockerill Company, where the party were welcomed by M. Delloye Matthieu, chairman, and M. Kraft, chief engineer to the society. Luncheon was subsequently served, and in the afternoon the Val St. Lambert Glass Works were visited, with M. Deprez, general manager, as guide. In the evening the summer dinner of the institution was held in the Salle des Vitraux of the Hotel Mohren, Liège, the chairman (Mr. H. J. Young) presiding. On Saturday, sectional visits were paid to the Small-Arms Works, the Liège electric tramway installation, the works of the Compagnie Internationale d'Electricité, the Liège Gasworks, and M. Fouldu's Iron Foundry. The party returned to England in the afternoon. At each place visited throughout the week, the Belgians were exceedingly cordial and generous in their welcome, evoking from their visitors expressions of the heartiest appreciation.

THE ANNUAL MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER AT MUNICH.

(BY OUR SPECIAL CORRESPONDENT.)

(Concluded from page 212.)

INTERVIEW WITH MR. EMIL KOLBEN.

Armed with an introduction from Mr. F. Drexler, the representative of the Oerlikon Works in Vienna, whom I had met at the Munich meeting, I made my way to Oerlikon. After some difficulty I succeeded in finding Mr. Kolben, who very kindly conducted me to his private office. We first compared notes as to our previous interview in London, when Mr. Kolben was there in 1892; and then I proceeded to put him on the rack.

"What is the usual system of town-lighting in Switzerland, Mr. Kolben?" I asked.

"In all towns," he replied, "where electric lighting is the chief *raison d'être* of the supply we use single-phase alternating currents, and in this system employ motors up to 10 h.p. or 12 h.p. In no case is direct current now being installed for large towns, as the cost of the mains is considered with us to be a prohibitive item. In some small

Emil Kolben.

villages, where the lighting is very compact and close to the source of power, we continue to use direct-current machines for lighting and power."

"What voltage do you usually employ?"

"We standardise our alternators and transformers in the following pressures: 1,000, 2,000, 3,000, and 5,000 volts. These pressures are generated directly in the alternators, and there are no transformers employed at the primary station, but for pressures over 5,000 we transform up. In fact, the Oerlikon Works are driven from a water-power installation 16 English miles away, and in this instance a pressure of 13,000 volts is used, with transformers at each end."

"In the town-lighting schemes designed by you, what cables do you employ?"

"The Swiss and German practice is to use lead-covered paper cables exclusively. These are laid usually in a stoneware conduit or trough, and in a few cases in cast-iron conduits. In other places the earthenware conduits are replaced by iron armouring on the cable."

"Now, as regards the works cost, Mr. Kolben. Do you consider that you are able to produce and sell electricity cheaper than we can in Great Britain?"

"We have no compulsory returns of the cost per unit, as you have in England, in the various electrical stations with which I have had to do. I cannot give the details so fully as you would like. I may, however, say that in Zürich, where the charge is 70 centimes (6¾d.) per kilowatt-hour, the authorities make a considerable annual profit out of the undertaking."

"Is not water power used at Zürich?" I queried, "and what does it cost?"

"For small units," was the answer, "the average charge about Zürich for water power varies from 200f. to 300f. (£8 to £12) per horse-power per annum, but if the company builds its own waterworks it often succeeds in reducing this figure."

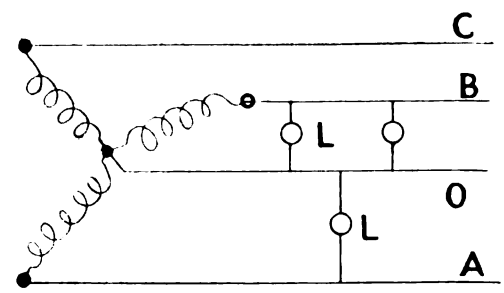

FIG. 1.—Three-Phase System with Zero Wire for Lighting.

"Apart from town-lighting schemes, what system would you adopt for transmission of power?"

"I use the three-phase alternating system for large transmission work if the main demand is for power, as with this the cost of the line is a minimum. If lighting is required on the same system, we sometimes use the star winding and run a neutral wire from a common junction. I then place the lamps between any one of the three wires and the neutral wire, and in this way the fluctuation of voltage when the branches are unequally loaded is to a large extent prevented" (Fig. 1).

"When you are starting single-phase motors, on lighting the circuits don't you find that they cause objectionable variations of voltage on account of the large starting currents they take?"

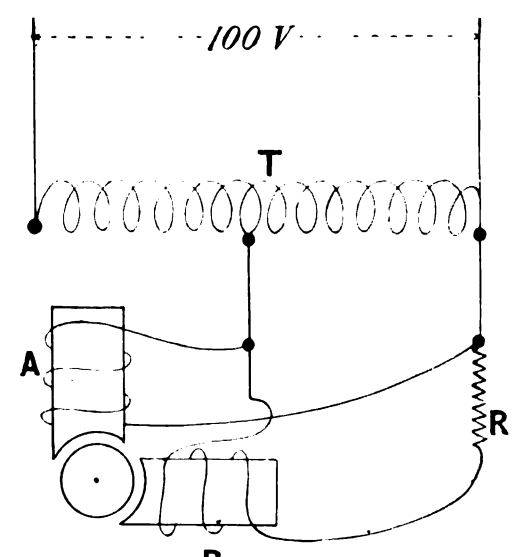

FIG. 2.—Diagram of Starting Connections for Oerlikon Single-Phase Motor.

"The method which I have devised and standardised for use with our motors is, roughly, as follows: Instead of using the full voltage when starting the motors, I employ a transformer in connection with the switch, so that the energy required to start a motor is attained at a low voltage by transformation (Fig. 2). In this way the actual current taken from the main in starting is always less than the normal working current of the motor, and with moderate-sized motors is often less than half. We also supply our motors with a fast and loose pulley arrangement, so that they are started free, or without load, and the frictional clutch introduces the load gradually if the motor has attained its speed" (Fig. 3).

Digitized by Google

"What do you consider the most interesting scheme of power and light distribution by electricity with which you have had to do lately?"

"We have erected at La Goule, in the West of Switzerland, single-phase electric lighting works of 1,500 h.p. From this point we supply a district having extreme points 16 English miles apart. The industry of the district consists of watch manufactories, and about a dozen small towns and villages are supplied with light and power. The charges for power are approximately as follow: 320f. (£13) per annum for a ¼-h.p. motor; 125f. (£5) per horse-power per annum for motors varying in output from 2 h.p. to 12 h.p. Overhead wires are used in this installation at a pressure of 5,000 volts."

guarantee for our standard frequency of 50 complete cycles per second should hold good even at such abnormal frequencies as 133 per second."

In walking through the works, the first machines which attracted my attention were some direct-current dynamos designed for the Aluminium Company of Scotland. Five of these machines are required, the output of each to be as follows: 8,000 amperes at 65 volts for running at a speed of 150 revolutions per minute. Mr. Kolben has designed these machines with 24 poles, the armatures being drum wound. One hundred and twenty brushes are used to collect this enormous current, and the weight of iron in the field magnets is about 17 tons. I was privileged to see the armatures of these machines in

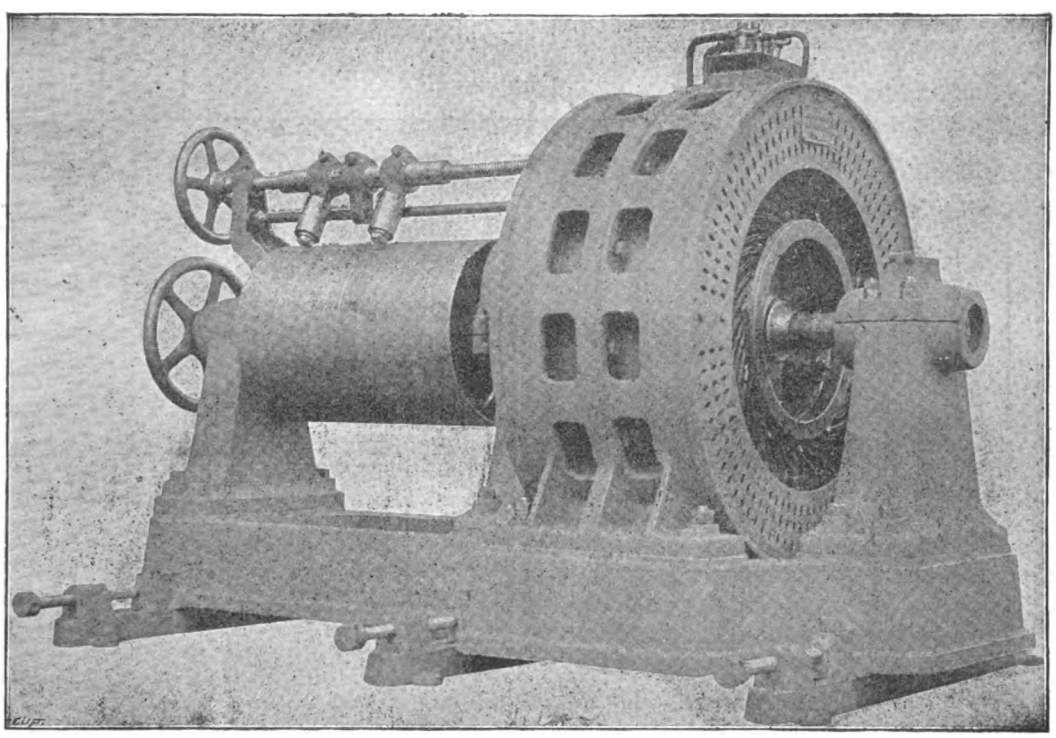

FIG. 3.—Oerlikon Single-Phase Motor, showing Fast and Loose Pulley

Mr. Kolben, after answering my questions, proceeded to put me through the same ordeal, and he manifested great interest in the various items of English news which I was able to give him. He then asked me to accompany him round the works, in order that I might see some of his designs in course of construction; but before starting I asked him what he thought of the prospects of electric motors on alternating-current circuits in England. He replied:

"I have found the greatest difficulty in answering the numerous enquiries that I receive from England for motors

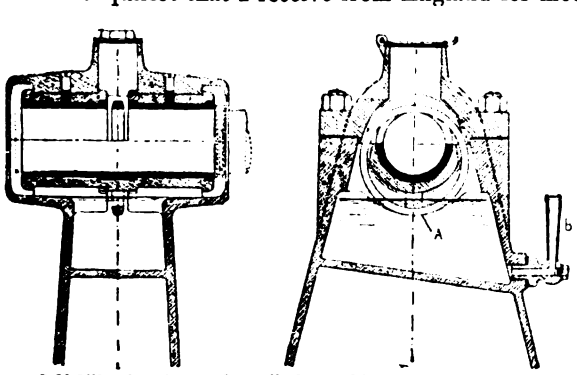

FIG. 4.—Self-Oiling Bearing used on all the Oerlikon Dynamos and Alternators.

on account of the great variations in frequency. It appears to me that you have in England frequencies of so wide a range as to render the standardising of electric motors almost impossible. Almost every enquiry that I get from your country requires either a new design or some large alteration of our existing types to ensure a reasonably efficient motor; and the idea seems prevalent that the figures we

various stages of construction, and was struck with the neatness of the design. Stranded conductors are employed, and to prevent the conductors flying outwards under centri-

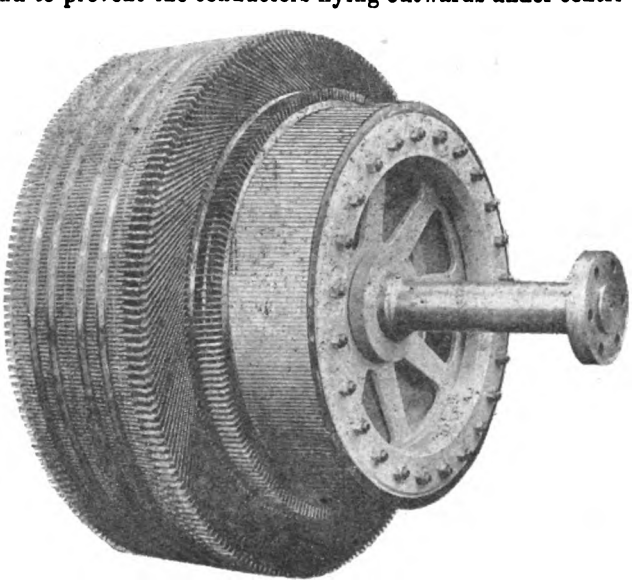

FIG. 5.—Armature of a Large Multipolar Oerlikon Dynamo.

fugal force they are threaded through holes in brass plates, which are bolted into the core. The diameter of the armature being 7ft. 3in., the circumferential speed of the conductors is 3,420ft. per minute. The ordinary binding-wire arrangement would not be a sufficient safeguard at this speed and diameter.

The whole of the machinery in the works is driven by

Digitized by Google

alternate-current motors. The power is derived from a water-power plant situated 25 kilometres away. The pressure employed is 13,000 volts, which is transformed down to 190 volts at the works for distribution to the various motors. Each motor usually drives a section of the line of shafting, but the larger machine tools have separate motors attached. The various details of construction in the dynamos and alternators turned out by the Oerlikon Company show that great care has been bestowed upon them. The ring method of obtaining constant lubrication has been universally adopted by this firm. Fig. 4 shows two sections of their standard bearing.

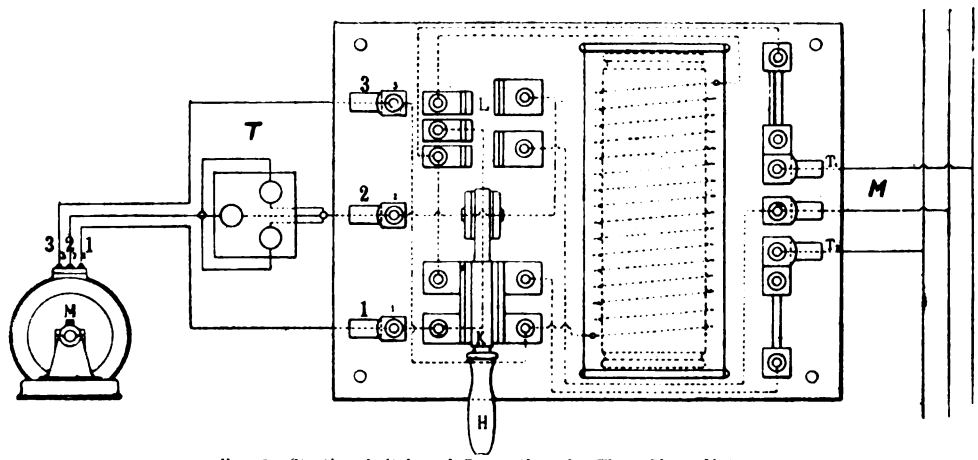

FIG. 6.—Starting Switch and Connections for Three-Phase Motors.

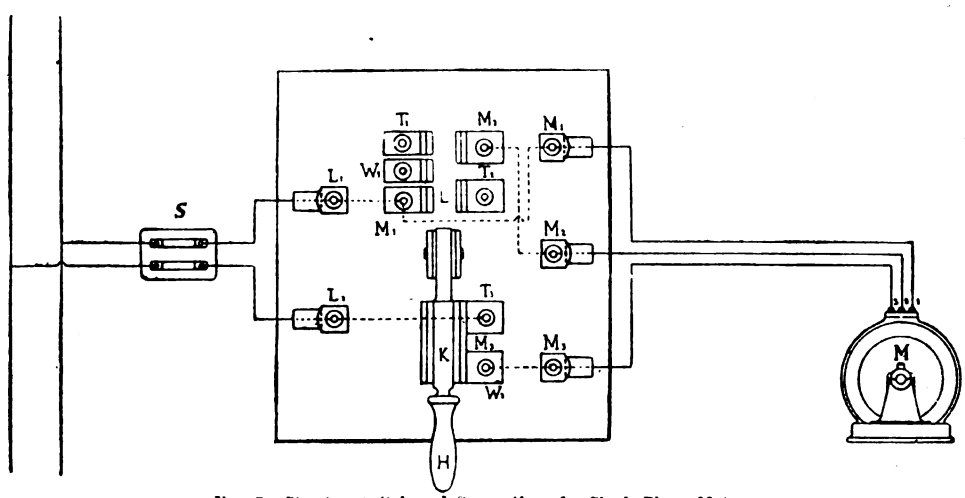

FIG. 7.—Starting Switch and Connections for Single-Phase Motors.

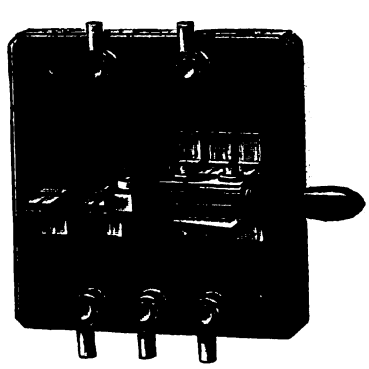

FIG. 8.—Starting Switch.

The following *résumé* is extracted from the instructions issued with the Oerlikon alternator-current motors, and will give a good idea of the connections used. Fig. 6 refers to motors on three-phase circuits, and Fig. 7 to single-phase alternate-current motors, Fig. 8 being a perspective view of the same. Steady foundations should be provided for the motor, which may preferably be mounted on wood to ensure good insulation from earth. The starting switch should be placed handy, and the connections made to it as shown in diagram. In starting, the belt must stand on the loose pulley, R_1 (Fig. 9), which must not be touching the fixed pulley, R. When the motor is not in use, the handle, H, of the switch (Figs. 6 and 7) is vertical, and does not make contact with either K or L. All being ready, the handle is moved over into the K position which gives an arrangement of connection similar to those described above by M. Kolben in this interview. The motor then starts and quickly reaches its normal speed. The note or hum given out tells the operator when this speed is attained.

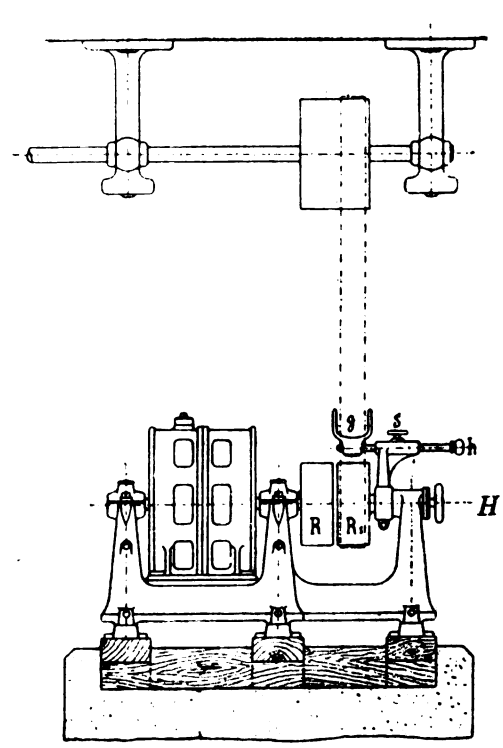

FIG. 9.—Fast and Loose Pulley Arrangement.

Digitized by Google

and the handle, H, should then be changed over into the L position as quickly as possible. The motor is then ready to be put on its work. This is done gradually by means of the fast and loose pulley gear. The hand-wheel, H, when screwed in causes the loose pulley, R_1, with the belt on it, to be driven by friction. The belt then can be slowly moved over on to the fast pulley, R, by means of the striking gear, *g* and *h*, which is clamped by the set screw, *s*. Both motions being gradually per-

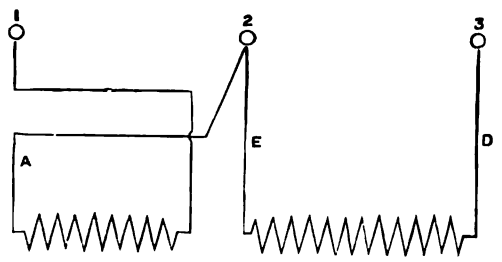

FIG. 10.

formed, the motor will never take an excessive current, or cause any fluctuation in the lights supplied off the same mains.

Should the direction of the motor need to be reversed for any reason, the connection of one winding only need be changed, Fig. 10. Care must be taken that the switch is never thrown first into the L position, and that after stopping, the loose pulley, R_1, is always left out of contact with the fast pulley.

PROF. THOMAS'S INCANDESCENT LAMP TESTS.

Prof. Benjamin F. Thomas, of the Ohio State University, Columbus, Ohio, has recently completed an elaborate series of tests on the "Packard" incandescent lamp, made by the New York and Ohio Company, of Warren, O. The report of the test is lengthy, and the following is a brief abstract of it:

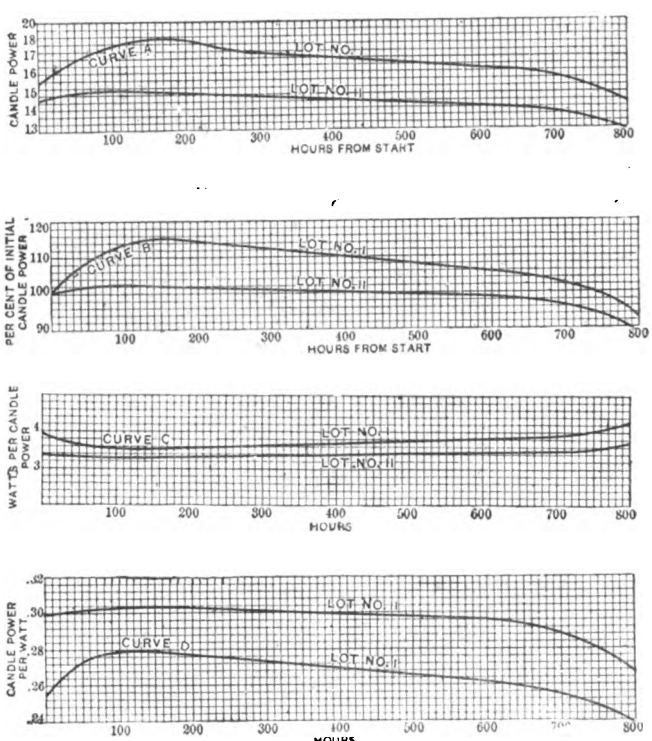
The tests were very carefully conducted, Weston measuring instruments and a Summer-Brodhun sighting-box adapted to an accurately-graduated portable photometer bar 100in. long being used. The results of the tests, showing the average of Lot No. 1, are given in the following table:

Hours from start of test.	Number of lamps burning	Candle-power.	Per cent. of initial candle-power.	Watts per lamp.	Watts per candle-power.	Candle-power per watt.
0	25	15·54	100	61·00	3·93	·254
96	25	17·58	113·2	63·12	3·59	·279
144	25	17·84	115·0	63 62	3·57	·280
192	25	17·82	115·0	63 54	3·57	·280
252	25	17·53	113·0	63 55	3 63	·275
312	25	17·30	111 4	63 41	3·66	·273
360	24	17·04	110 0	63·30	3 70	·270
408	24	17·08	110 0	63·30	3 70	·270
480	24	16·68	107·5	63 00	3 88	·265
528	24	16 70	107·5	62 73	3 76	·266
600	24	16·35	105·3	62 64	3·83	·261
648	23	16·07	103·4	62·60	3 90	·256
696	22	15 83	102·0	62·60	3 95	·253
768	22	14 81	95 3	61·94	4·17	·240
812	22	14·50	93·3	61·51	4·24	·236

The electric readings were taken by two experienced students, Messrs. A. H. Jones and R. D. McCarter, jun. One hundred lamps, labelled "16 c.p., 100 volts," were obtained for this test. They were about equally divided in two lots, having distinguishing marks inside the bulbs. Twenty-five lamps were taken at random from each lot for test.

The voltage was not perfectly constant, and no attempt was made to secure unusual constancy, for the reason that the circuit arrangement used enabled us to work the lamps under the conditions ordinarily existing in central-station practice. The results may therefore be considered as a better indication of what lamp users may reasonably expect from similar lamps, than if the lamps had been run at an unvarying voltage. From readings taken on different days and at different times of day, I think the average voltage was about 99.

The values of Tables I. and II. (the first is the only one given here) are plotted in terms of candle-power and time in Curve A, of percentage of initial candle-power and time in Curve B, and of efficiency and time in Curve C. As shown by these curves, Lot I. shows a marked increase in candle-power on the start, reaching a maximum of 17·9 candles at about 175 hours, then decreases uniformly until 600 hours, when a more rapid decrease sets in. The candle-power does not fall to its initial value of 15·54 candles until over 700 hours from the start. Lot II. shows only a moderate rise in candle-power with a maximum at about 150 hours, and then decreases uniformly to its initial value at 400 hours. It shows also a sharp increase in declining brightness at 600 hours. This change may have been produced by strain due to abnormally high voltage at soon after the 600-hour point. Such a high voltage was observed for some time during the day preceding the evening on which the readings at 696 hours were taken. Curve C shows a marked increase in efficiency for Lot I. on



the start, falling back to the initial value only after 600 hours. Lot II. improves in efficiency also at the start, though to a smaller extent, and continues at a practically uniform figure for 600 hours. The decrease in efficiency for each lot after 600 hours is much less rapid than usually met with.

It will be noticed that the breakage is remarkably small. No lamp of either lot showed any serious blackening, and the majority of the lamps were scarcely blackened at all.

The report ends by saying that, taking economy, maintenance of candle-power, and freedom from blackening into account, the results obtained are much superior to any heretofore published.

TEST OF TWO CASTLE MOTORS.

Last week a most interesting test of two 150-h.p. "Castle" motors was conducted at the works of Messrs. J. H. Holmes and Co., at Newcastle-on-Tyne. These motors, which are to be exported to a firm in South America, have been built to a most rigid specification.

The motors were drum-wound, the armatures being constructed after the methods standardised by this firm. The connectors are so designed that the connection to the brushes are made at the centre of each connector, this method giving horizontal position to the brushes. The motors before being accepted had to be run continuously

Digitized by Google

for 24 hours at full load, and to have a commercial efficiency of 92 per cent., together with a low temperature rise in both armature and magnets.

As a full-load run of this duration is both expensive and difficult to arrange where the power is absorbed on a brake, Mr. J. H. Holmes determined to test the two motors by the Kapp method. In this way the actual power to be supplied is limited to that corresponding to the electrical and mechanical losses in the two machines at full load. The arrangements of test were as follows: The two motors were bolted on to a combined frame, Fig. 1, and geared together by a guttapercha belt, the torsion in which could be adjusted by moving one of the machines on its rails in the usual manner. The armatures were then connected in series, as shown diagrammatically in Fig. 2.

In the circuit a small generator was also connected to supply the necessary power. This series method was adopted because a suitable dynamo giving 600 amperes was available, and there was little difficulty in driving it at the low speed in order to obtain about 35 volts. The series method also has the advantage over the method by which the power is supplied at the normal voltage, that the readings for determining the efficiency are obtained from a voltmeter instead of from ammeters. One voltmeter with a two-way switch, with the connections as shown, gives the two readings necessary. The field of the two machines were each connected in shunt across the brushes of their respective armatures. Regulating rheostats, R R_1, were inserted, and enabled the field to be varied to get the corrected current, speed, etc. During the trial the current in the main circuit was read on a Weston milli-voltmeter, A, measuring fall of potential at the ends of a standard resistance in the circuit. The voltmeter, V, was also a Weston instrument.

In starting up, the field of the machine, M, which was to act as the motor in the combination, was strengthened, and that of the dynamo, D, weakened. The loss in the conversion of power is then supplied by the auxiliary dynamo, X, which was separately excited. After the adjustment of the rheostats to get the correct speed, current, and voltage had been made, the eight following readings for the efficiency test were obtained:

Motor.			Generator.			Time.
Volts.	Amperes.	Revs.	Volts.	Amperes.	Revs.	
216	600	522	182	600	514	9.30 a.m.
212	539	499	179	530	492	11 ,,
216	590	500	183	590	495	11·30 ,,
214	600	506	181	600	501	11·45 ,,
215	600	508	182	600	503	12 ,,
215·5	604	510	182·5	604	503	12.15 p.m.
216·5	615	512	183 5	615	503	12.45 ,,
213	600	534	180	600	522	1.15 ,,

The mean of these first readings gave the voltage on the motor as 215 volts, as compared with 184 volts on the dynamo. If the two machines were rigidly geared, these figures would give the efficiency direct, but in this case the mean speed of the motor was 511 revolutions per minute, and that of the generator 504·1 revolutions per minute. This shows a belt-slip of 1·42 per cent., as the pulleys were of the same diameter. Hence a correction must be applied to the volts obtained from the generator, as without the belt-slip the speed of it would be 1·42 per cent. higher, and the voltage would be increased by an amount depending on the efficiency of the dynamo. Assume this to be 92 per cent., the correction in the voltage will be

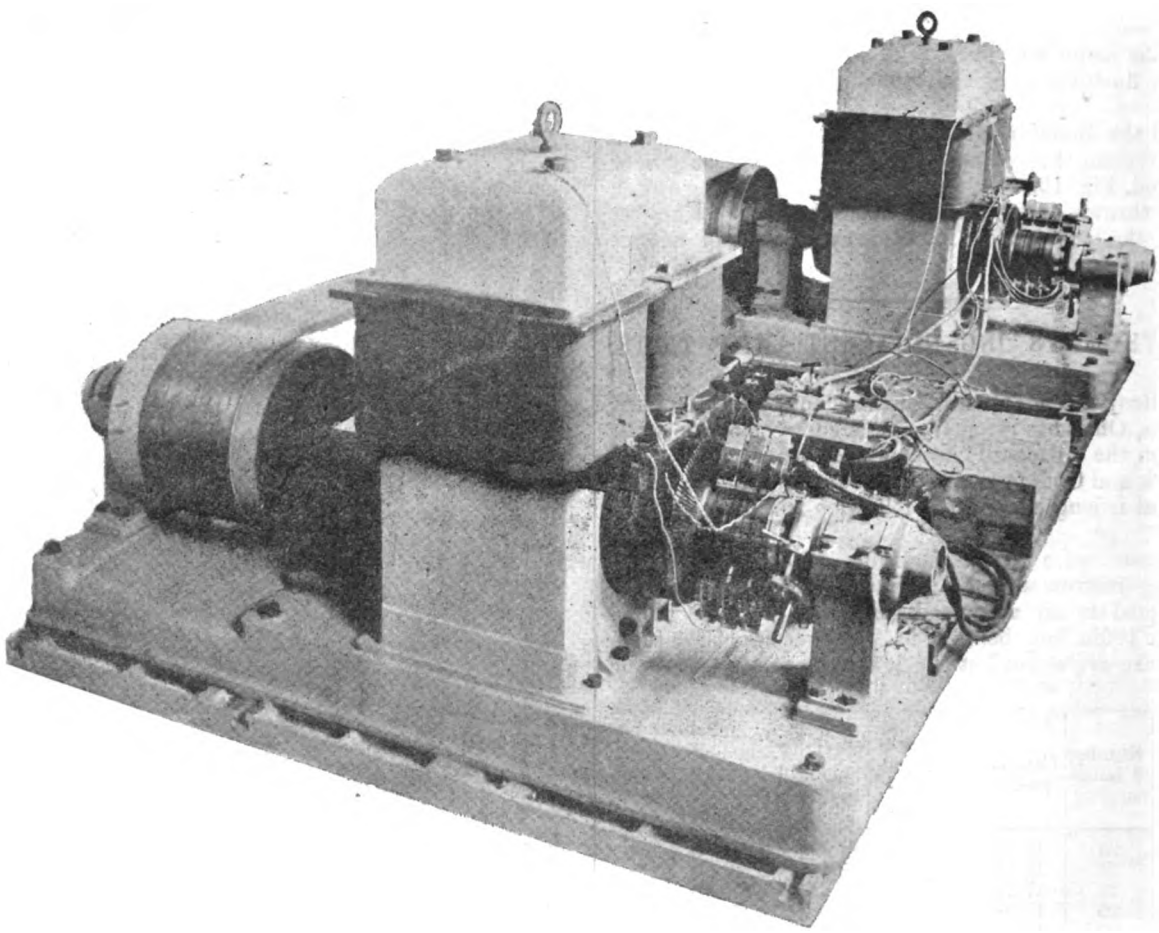


FIG. 1.—View showing the Two Castle Motors as Mounted for Efficiency Test.

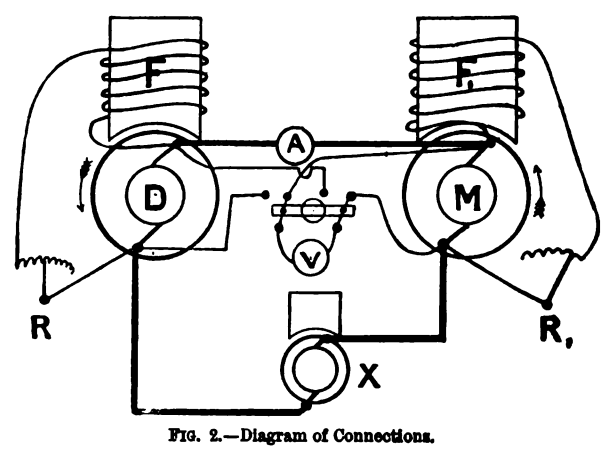

FIG. 2.—Diagram of Connections.

Digitized by Google

1·42 × ·92 = 1·3 per cent.

Then 184 × 101·3 = 186·4 volts will be the figure corrected for belt-slip.

The efficiency of the combined set is then obtained by simple proportion.

215 : 186·4 :: 100 : x, from which $x = 86·7$ per cent., and the individual efficiency is then the square root of this, which gives the high figure of 93 per cent. as the commercial efficiency of each machine. The rheostats were then readjusted, so that the motor gives 150 b.h.p. to the driving belt, and the run continued for 24 hours. The following readings were taken at intervals, being a continuation of the previous table:

Motor.			Generator.			Time.
Volts.	Amperes.	Revs.	Volts.	Amperes.	Revs.	
200	608	514	169	608	514	1.30 p.m.
200	608	515	169	608	514	2 15 ,,
199	600	502	168	600	495	2.45 ,,
200	595	503	169	595	497	3.15 ,,
197	580	520	167	580	490	8.45 ,,
198	600	510	169	600	490	9.30 ,,
200	608	506	169	608	500	10.15 ,,
203	608	510	172	608	502	12.15 ,,
204	608	509	172	608	508	11.15 ,,
201	605	508	170	605	506	—
199	590	508	168	590	502	2 30 a.m.
195	580	495	164·5	580	487	3.25 ,,
200	585	486	169	585	486	4.30 ,,
197	580	497	166	580	486	5.30 ,,
200	596	502	169	596	494	6.30 ,,
209	600	514	178	600	508	7 30 ,,
202	600	500	172	600	496	8.0 ,,
198	600	514	168	690	506	8.45 ,,
201	610	506	170	610	502	9.15 ,,

The motor was thus kept fully loaded throughout the trial, while the generator was slightly underloaded.

The temperature tests taken show that the heating of the armature had attained its maximum value long before this trial was completed.

Temperature Rise in Armature.

	Motor.	Generator.
After 6 hours' run	35deg. F.	41deg. F.
,, 12 ,,	75 ,,	60 ,,
,, 18 ,,	76 ,,	58 ,,
,, 24 ,,	74 ,,	63 ,,

At the end of the trial the temperature of the exciting coils on the magnets was in the motor some 53deg. F. higher than that of the surrounding air, and in the generator 39deg. F.

The above tests were carried out under the inspection of Mr. Farquharson, late of the Admiralty, on behalf of the buyers.

We congratulate Messrs. J. H. Holmes and Co. on the excellent results of this trial.

LOCATION OF GROUNDS IN ARMATURES, FIELDS, ETC.*

BY CLARENCE E. GIFFORD.

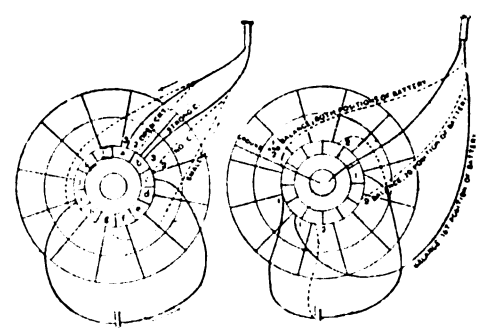
This paper presents no novel scientific principles. The methods herein described are but simple adaptations of the principle of the Wheatstone bridge. If the work can be performed in a very quiet room, two or three cells of battery, a telephone receiver, and connecting wires comprise the necessary apparatus. In some cases two "table binding posts" and a foot or two of No. 18 or No. 20 bright iron wire will be a convenient addition. Where noise will not permit the use of a telephone, a dead-beat reflecting galvanometer, a milli-voltmeter, or some other form of delicate and rapid working visual indicator must be used instead. If an armature is to be tested without removing it from the machine, connection with the battery may be made through the brushes, first making certain that the short-circuiting switch is opened, if dealing with an arc machine. The points of connection with the battery need not be diametrically opposite, and may be made by the wires being firmly pressed against the commutator by an assistant, if more convenient.

* Paper read at the twelfth general meeting of the American Institute of Electrical Engineers, Niagara Falls, N.Y.

Good electrical contact between metallic surfaces can better be secured by cleaning the same thoroughly with kerosene, which removes foreign matter, and is so fluid that it will in no way interfere with perfect contact when moderate pressure is applied. Especially when making measurement of resistance of armature sections, it is even advisable to have the surface of the commutator quite wet with kerosene during the operation, as this avoids trouble from grease or dirt which might get on the surface from handling, subsequent to cleaning, and it also prevents the contact points becoming oxidised by any sparks which may occur at the moment of breaking contact. True, the oil is an insulator, but we use it in this case as a detergent simply.

Returning to the armature, connection being made between battery and commutator, first determine whether the armature circuit is complete throughout. If the circuit is complete, a click will be heard in the telephone when the two terminals of the same are brought in contact with any two contiguous bars of the commutator, or when contact is broken. If an open circuit exists on either side of the circuit of course no sound will be heard in the telephone when used on that side, except when connection is made or broken by it between the bars lying on opposite sides of the break. (See Fig. 1.)

Close any open circuit temporarily by bridging between the two bars with a drop of solder. Two or more breaks can evidently be located by suitably shifting the battery contacts and searching as before. Open circuits will, of course, when an armature continues in work, soon cause burns between the bars that will indicate unmistakably their location. Having closed any open circuits, and the



Figs. 1 and 2.

battery being connected to two points of the commutator, approximately opposite each other, one terminal of the telephone is connected to the armature shaft, or frame of the machine, and the other terminal is drawn completely around over the surface of the commutator, while the telephone is held to the ear. If only one ground exists, two balancing points, or points giving the least noise in the telephone, will be found.

In an armature of ordinary construction, one of the points so found will be on the bar nearest the real ground, while the other balancing point bears what might be termed a "bridge relation" to the first, being at practically the same potential; the armature itself forming in reality a veritable Wheatstone bridge. Now shift the points of battery contact a few bars either way, and the true ground, if but one exist, will be indicated in precisely the same position as before, while the other balancing point will shift every time the battery contacts are shifted. (See Fig. 2).

If two grounds exist, two balancing points will be found, as before, but both points will shift more or less when the battery contacts are shifted, provided the grounds lie on opposite sides of the same battery contact. This case will be considered later.

In the case of one ground, having determined its location approximately, fix it as closely as may be by making and breaking contact with the telephone terminal on each of the more quiet bars, separately, until, by comparison, the two giving the faintest clicks are determined. If your hearing has served you correctly, these two bars lie nearest the trouble, the fainter one being the nearer. Prove the non-existence of a second ground by placing one of the battery contacts on the first bar to the right of the apparently

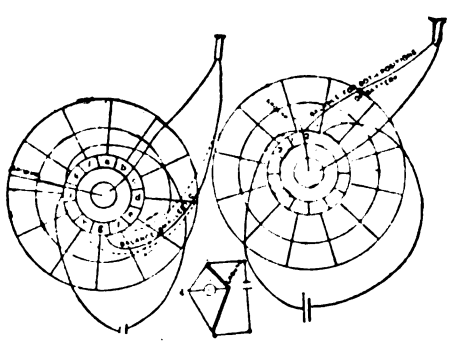
Digitized by Google

permanent balancing point just found, and then on the first bar to the left of said point, the other contact being nearly diametrically opposite. This balancing point should still remain unchanged if no other ground exists.

The next step is to connect the battery to these two bars just fixed upon as lying nearest the trouble. The armature still forms a "bridge," the portion included between the two contiguous bars to which the battery is now connected forming the one side, and the remainder of the armature the other side. (See Fig. 3.)

One of the telephone terminals is now connected to the shaft as before, and the other terminal again drawn around the commutator. If the balancing point is found, say, one-sixth to one-half the long way around from one battery contact to the other (these contacts being on two contiguous bars), the trouble lies in the coil between those two bars, and the point of trouble divides the coil in the same ratio as the balancing point divides the remainder of the armature, the ground and the balancing point being respectively nearest the same battery contact. If the balancing point falls on the same bar as one of the battery contacts, the ground is located on that bar or on the lead between it and the armature, provided the balancing point is found to be upon the same bar when the battery contacts are both shifted one bar to the right or left of their original position. (See Fig. 4.)

If the balancing point appears to be found within three or four bars from one of the contacts, the precaution should be taken to test its correctness by moving both battery contacts one bar toward the balancing point. If the trouble was between the battery contacts when in their previous position, this shifting of the contacts will now throw the balancing point clear around on to the contact, which was,



FIGS. 3 AND 4.

in the previous position, farthest away from the balancing point. If, on the contrary, the balancing point remains unmoved by this shifting of the battery contacts, it shows that this balancing point is the point nearest the real ground, and that the ear was deceived in its first supposed approximation, which, with due care, however, is not likely to occur.

If such error has been made, the new point, as indicated, together with first the bar on one side of it and then on the other, must be tried as points of battery contact, or, much better, make a new start with the contacts nearly at opposite sides of the commutator and proceed as before. A single 20,000-ohm ground on a one-ohm armature should be located accurately in not over three minues, in a quiet room. Higher resistance grounds require more battery and more care. Armatures of very low resistance also offer greater difficulty.

Where two grounds are found to exist, as indicated by the change of location of both balancing points, under the conditions before stated, when the battery contacts are shifted, the following mode of procedure will answer the purpose well, and is simple. Fix the battery contacts at any two points of the commutator nearly opposite each other, preferably at points to be determined by trial, that will cause the balancing points to fall nearly diametrically opposite to each other, and determine and mark the two balancing points, as then shown. Now place the battery contacts on the balancing points just found. If only one ground exists, the two balancing points and one battery contact will all be coincident in one point. If two grounds exist, both balancing points will be shifted from their former position. Open the armature circuit by unsoldering one of the ends of a coil connecting with the lead of the bar that is marked in the first part of this test, as one of the balancing points. Place one of the battery contacts on the armature shaft, and the other on the marked balancing point that is farthest from the point where the circuit has been opened. Next place one telephone terminal on the first bar to the right of the opened wire, and draw the other terminal from the same point toward the right, over the surface of the commutator. The telephone will be absolutely silent until the moving terminal has just passed the ground nearest to it, and strikes the first bar beyond the same, when it will click. This ground lies in the coil between this first bar giving a click and the one passed just previously, or else in the said previous bar.

The other ground is obviously to be located in a similar manner, by placing one telephone terminal on the bar just to the left of the open wire, and from that point searching toward the left with the other terminal. Only in cases where one ground is of very low and one of very high resistance will any difficulty be experienced in locating both accurately before either is removed.

The coils thus indicated may have their terminals unsoldered, when it can be readily ascertained with each whether the ground be in the coil or in the bar just preceding it.

If scientifically inclined, or if otherwise preferable, the circuit may be opened at a point somewhere midway between the two indicated coils instead of disconnecting those coils, and the exact location of each ground determined as follows: Take a piece of "broom wire" about 18in. long, new and clean, screw the ends firmly into two clean brass table binding posts, and into the other holes of the same posts screw the battery terminals. Have an assistant press the corners of the bases of the binding posts into very firm contact with the two bars that lie at the ends of the indicated coil, observing the directions previously given for securing clean contact. Place one telephone terminal in contact with the shaft, and with the other find the balancing point on the wire. This point will indicate the relative position of the ground in the coil or commutator bar, as the case may be. If more than two grounds were suspected, the two lying the farthest apart would be approximately located by the first part of the two-ground process, and if these coils were not disconnected before proceeding farther, it would be well to make two openings in the circuit, close to and lying between these outer grounds; then locate definitely these two extreme grounds and proceed with the remaining section somewhat as with a complete armature, except that you would commence by connecting the battery to the terminals of this section, and would then bridge the telephone from the shaft to the different portions of the section and would complete the process by applying the remainder of the two-ground test.

In dealing with a cross-connected Gramme ring, an obvious change would be made in the points of application of the battery, and as many points of apparent trouble would be indicated as there were series of cross-connections.

After location of these points it would be necessary to use the auxiliary wire loop, as before described, between these points, to determine which is nearest the trouble. This fact being determined, it would in case of a single ground (indicated by the permanency of the balancing point) become necessary to remove the cross-connections from two bars before proceeding farther. The auxiliary wire loop would properly be used to complete the process.

The ordinary "closed-coil" ring or drum armatures are types to which these methods are directly applicable.

The sections of open-coil armatures would receive the same treatment as field coils.

Familiarity with any special forms of armature will doubtless suggest to the ingenious mind modifications of these methods suited to those forms, but it would be improper to attempt here to deal with specialties whose names are legion.

Where wet grounds exist it will always be better, when practicable, to dry them out before making the final test, as certain sections may show faults which will not be permanent. Wet grounds will, of course, give a click in the

Digitized by Google

telephone when bridged from the commutator to the shaft when no battery is attached, owing to galvanic action of the water on the copper winding and the iron core.

Whenever necessary to deal with wet grounds in testing, it is better to make at least four tests, reversing the battery after each test, and taking the mean of the four determinations.

Field coils, also any wires of uniform cross-section, the extremities of which are accessible and within a reasonable distance of each other, can, of course, be easily tested for grounds by soldering or firmly clamping a bare wire of suitable size between the extremities of the conductor to be tested, applying a battery to the junctions, and bridging with a telephone between the bare wire and the object upon which the conductor is grounded. This will give only the location of a single ground, or the "resultant" of two grounds. A "T. H." rheostat should have the battery connected to the two extremities, and the point of apparent ground determined by bridging with a telephone between the frame and the several contact plates. Then apply the battery to the frame and point of apparent ground, connect one terminal of the telephone with each extremity successively, and search from it toward the centre with the other terminal, as in the case of searching for two grounds in an armature.

In determining the location of grounds that are of very low resistance, a good induction coil similar to that used in the Blake transmitter may be used with advantage in connection with the telephone receiver. The receiver is placed in circuit with the secondary of the coil, and the "bridging" is done with the primary. With high-resistance grounds the best results are obtained by using the receiver only.

ASSOCIATION OF MUNICIPAL ENGINEERS.

A discussion followed Messrs. Christie's and Perry's papers read last week at the Londonderry meeting of the above-named association, and given in our last issue.

Mr. T. DE COURCY MEADE drew attention to the peculiar fact that the Londonderry lighting was for public lighting only, and that no provision had been made for private distribution. That policy differed from that of other municipalities, and, particularising Manchester, he pointed out that the whole power there was taken up in providing for public lighting, that extensions were being made, and he had no doubt these would be similarly utilised for private lighting. He thought the municipality was greatly handicapped by restricting its work in one direction only.

Mr. PRITCHARD (Birmingham) also considered it singular that the lighting was confined to street-lighting only. He agreed that arc lighting was the suitable light for large areas, while incandescent lighting was suitable for house or interior lighting. With regard to Mr. Perry's paper, he did not think that municipal engineers would generally become electricians or electrical engineers, but would allow the specialists to continue to work in that direction. The electrician, though, perhaps, not so bad as he was painted, generally tried to minimise his blunders by saying he was not a practical man, or, as Mr. Pritchard put it, "A'wm no practical." Referring to the use of electricity for traction, he gave his experience of accumulators—that they were far too costly and too fragile for the work.

Mr. LOBLEY (Hanley) said he could explain one or two of the circumstances referred to in the paper. In the first place, it must ever be remembered to the credit of Londonderry that the town was one of the pioneers in municipal lighting, and then when the scheme was entered upon by the Municipality no doubt more attention was given to the street than to private lighting. It was practically certain, however, that the latter must sooner or later be undertaken. It was a courageous thing for Londonderry at that early period to touch the subject at all, and he thought other municipalities owed a debt of gratitude to the city for showing them it could be done. Public lighting was an excellent advertisement and an inducement for private lighting. He did not agree with the present photometric measurement of lights in candle-power. The calling of an arc lamp 2,000 c.p. was misleading, and the same might be said of the ordinary gas-burner, which was 15 c.p. or 16 c.p. nominal only, not real. He thought that incandescent lamps might be useful in the back streets, but undoubtedly arc lamps must be used for the wide and busy streets. He agreed so far with Mr. Perry, that he thought the only man who should have the control of the streets for laying and repairing mains was the borough engineer. As regarded the cost of incandescent lighting compared with gas lighting at Hanley, the free library was wholly lighted by electricity, and it cost 15 per cent. more than when lighted with gas, but it was to be recollected that the amount of light was 50 per cent. greater. There was really no comparison between the two. Over his own desk he used to have two gas burners and could never get a good light; these he replaced by one 16-c.p. incandescent lamp, and his desk was now admirably lighted.

Mr. BROOM (St. Helens) thought that the borough engineer who undertook the design of a large installation would be a very courageous man.
